Dear Ms. Newman:

The report entitled "St. Louis Ordnance Plant Environmental Study Status Report" and dated November 1991 is enclosed for your review. The area of study in this report is that portion of the Hanley Area which remains under the ownership of the U.S. Army Engineer Center and Fort Leonard Wood.

Any questions concerning the above should be addressed to Mr. Robert A. Snyder at (410) 671-1510.

Sincerely,

Enclosure

Robert J. York
Chief
Installation Restoration Division

Dear Ms. Newman:

The enclosed document "Report DRXTH-FS-TR-81105 - SURVEY OF HAZARDOUS/CHEMICAL AREA NO. 2 OF THE FORMER ST. LOUIS ORDNANCE PLANT - Volume I" is being provided in response to the December 5, 1994, telephonic request of Mr. Jim Daly. Mr. Daly advised that a Summary Report on the former St. Louis Ordnance Plant is being prepared and this document was not available in your files. Mr. Daly's request for this document has been coordinated with the US Army Engineer Center and Ft. Leonard Wood Environmental Office.

Sincerely,

Karl J. Daubel
Environmental Coordinator

| 13. ABSTRACT (Maximum 200 words) A site contamination assessment was performed at the Hanley Area of the St. Louis Ordnance Plant located in St. Louis, Missouri. Twenty-nine surface soil samples were collected across the site to evaluate contamination potentially affecting surface runoff and windblown dust. Two water samples were collected from within the tunnel system. A screening survey was performed and samples collected to determine the extent of asbestos-containing materials (ACMs) within the tunnel system. Results of the sampling indicated that surface soils are contaminated with lead at levels of potential concern. Water samples collected were contaminated with lead and an explosive at levels of potential concern. ACMs are present in most areas within the Hanley Area, some of which should be removed and/or repaired. Recommended remedial actions are described in the report and include confirmatory soil sampling and asbestos abatement. | | | | |

EXECUTIVE SUMMARY

ICF KE was tasked by the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) to conduct a site contamination assessment of the Hanley Area at the St. Louis Ordnance Plant (SLOP), St. Louis, MO. This report describes the investigative methods used in and results of the study. A total of twenty-nine surface soil samples were collected across the site to evaluate the presence of contamination potentially affecting surface runoff and windblown dust. Two water samples were collected from standing water within the tunnel system as an indicator of whether off-site migration via surface routes was occurring. A screening survey was performed and eleven samples were collected to determine the extent of asbestos-containing materials (ACMs) within the building and tunnel system.

The results of the contamination assessment indicated that surface soils are contaminated with lead at levels of potential concern. Contaminant migration pathways include surface runoff and windblown dust. Water samples collected from the tunnels were contaminated with lead and possibly an explosive at levels of potential concern. Although the main source of standing water in the tunnels has been removed, water from infiltration and surface runoff may still enter the tunnel system, possibly carrying contaminants with it in the process.

Buildings, bunkers, and possibly the tunnel system contains metals and explosive contamination which may have contributed to soil and water contamination. Disrepair of the structures has exacerbated this situation.

ACM are present in most areas within the Hanley Area, and some of these materials should be removed and/or repaired. The ACM problem associated with potential demolition or renovation activities will be particularly severe.

A leaking transformer containing a high concentration of PCBs contaminated a limited amount of soil. The transformer has been demounted and protectively wrapped, and both the transformer and contaminated soils are in the process of being properly disposed of.

Enhanced restriction on access to the site, as well as confirmatory soil sampling at certain points within the Hanley area was recommended. Access to the tunnels and basements from the eastern side of Goodfellow Boulevard should be permanently blocked.

Buildings should be repaired to minimize inflow of rainfall and resulting runoff (via the land surface or the tunnels) of contamination. Demolition of former production Buildings 218A, 218B, and 218C and filling/capping of the basement cavities should be considered to further reduce these contaminant sources. Demolition of buildings within the magazines where contamination has been found also should be considered. Long-term planning should address whether the basements of buildings, if properly engineered, could be permitted as an approved on-site asbestos landfill.

The powder wells and associated piping should be characterized to determine whether contamination is present, then excavated and disposed.

It was recommended that the Army explore options for appropriate management of the asbestos situation in the Hanley Area at SLOP, without the need for complete removal of all ACM. The first priority in asbestos removal should address aboveground, potentially friable ACM (particularly Buildings 218A, 218B, and 218C), and removal of these materials should precede any demolition (if planned) or further deterioration of the structures. Asbestos elsewhere in the Hanley Area, at a minimum, should be monitored for changes in the potential hazards posed. Three different ACM abatement options were offered in this report.

1.0 INTRODUCTION

1.1 OVERVIEW

Under Contract No. DAAA15-88-D-0009, Task No. 3, ICF Kaiser Engineers (ICF KE) was tasked by the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) to conduct a site contamination assessment of the Hanley Area at the St. Louis Ordnance Plant (SLOP), St. Louis, MO. This report describes the methods and results of the study to determine the presence and extent of contamination at the site.

1.2 SCOPE AND OBJECTIVES OF THE SITE INVESTIGATION

The purposes of the site investigation were to: (1) identify the cleanup problems associated with the potential presence of asbestos-containing material (ACM) inside the buildings and within the underground utility tunnels; (2) determine the potential for contamination migration by surface routes through the underground utility tunnels which underlie the site; and (3) evaluate the extent of surface soil contamination around the buildings at the Hanley Area and the potential for contamination of groundwater. These objectives were met by assessment of sampling and analysis data obtained during the present study and data from past environmental studies at the Hanley Area.

1.3 REPORT ORGANIZATION

This site assessment report consists of eight sections. Section 1.0 serves as an introduction and describes the scope of the investigation and its objectives. Section 2.0 presents historical information about the site, describes the physical setting, and presents results of earlier environmental studies within the Hanley Area. Section 3.0 describes the screening surveys conducted in the present study, including the sampling methodology, decontamination procedures, and chain-of-custody procedures. Section 4.0 describes the regulatory criteria used to assess the sampling and analysis data. Section 5.0 provides a discussion of the quality assurance aspects of the sampling and analysis activities at the Hanley Area. Section 6.0 presents the results of the asbestos, tunnel water, and soil analyses and an assessment of environmental contamination at the Hanley area. Section 7.0 provides a summary of conclusions, identifies data gaps, and lists recommendations for additional work for the Hanley Area associated with decontamination of buildings, sewers, powder wells, asbestos, tunnel water, and soil. Section 8.0 provides references consulted in the process of writing this report.

2.0 BACKGROUND

This section presents information that is known regarding the St. Louis Ordnance Plant (SLOP) and more specifically, the Hanley Area. This includes information on the site history, physical setting of the area, and a summary of potential environmental problems identified at the site as a result of previous investigations.

2.1 SITE HISTORY

The St. Louis Ordnance Plant is located on the northwestern border of the city of St. Louis, Missouri, where it joins with St. Louis County (Exhibit 2-1). Most of the installation is located within the corporate limits of the city of St. Louis. The total original area of the installation is 279.5 acres. SLOP ended ordnance production in 1969, but subsequent use has been made of a portion of the installation for explosives production through lease to private industry. Since the 1970s the U.S. Army has transferred large portions of this acreage to various federal and city government entities.

The Hanley Area at SLOP is a 14.7-acre parcel previously leased to Hanley Industries for research, development, manufacture and testing of various explosives and munition components. Historical records indicate the likelihood that other munition manufacturing operations occurred within the Hanley Area during the period when SLOP was an active ordnance production facility. Previous limited studies have shown that contamination residues are present on building surfaces within the area, but the potential for off-site migration and, therefore, the requirements for remediation were not known. Previous studies also did not address the potential asbestos problems at the site.

The area formerly known as Hazardous/Chemical Area No. 2 consists of approximately 28 acres. This area of the facility remains under the ownership of the U.S. Army's Fort Leonard Wood (FLW). The Department of Labor (DOL) operates the St. Louis Jobs Corps Training Center on approximately 13 acres of Hazardous/Chemical Area No. 2. The remaining 14.7-acre Hanley Area is the subject of this report (Exhibit 2-2).

Much of the following information on the history of operations at SLOP was obtained from a report entitled "Survey of Hazardous/Chemical Area No. 2 of the Former St. Louis Ordnance Plant," prepared by the US Army Toxic and Hazardous Materials Agency, Aberdeen Proving Ground, and dated June, 1981.

2.1.1 Chronology of Operations - General

1941 The St. Louis Ordnance Plant (SLOP) was constructed between January of 1941 and May of 1942. Initial production of ammunition began as early as December of 1941. During World War II the facility was operated as a Government-owned, contractor-operated (GOCO) plant for the production of small arms ammunition and components for 105 mm shells. Three contractors occupied the facility during the periods when various ordnance items were produced.

1941-1957 Contractors

- The United States Cartridge Company (U.S. Cartridge), a subsidiary of Olin Industries, manufactured small arms ammunition. U.S. Cartridge occupied Plants 1 and 2 (187 acres) as identified on the outlease map of SLOP shown in Exhibit 2-3. This company is reported to have produced 67 million rounds of ammunition (USATHAMA, 1981).

EXHIBIT 2-1

ST. LOUIS ORDNANCE PLANT AREA MAP

(From: USGS 7.5' Clayton Quadrangle)

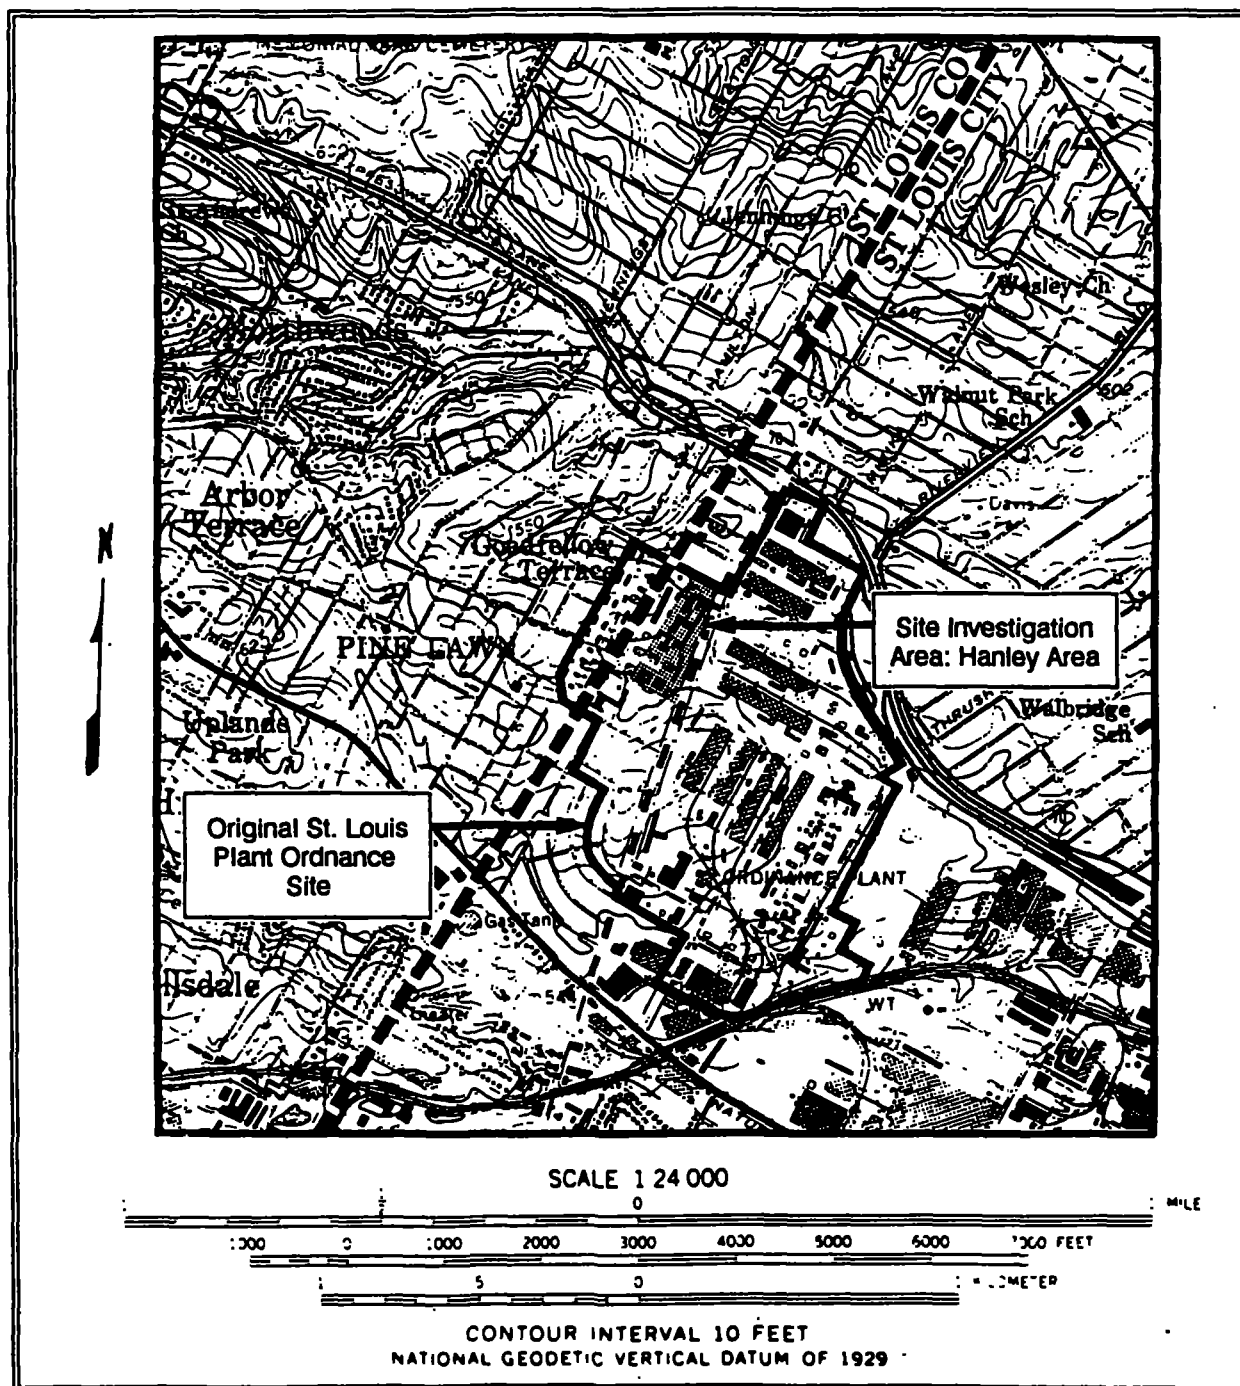

EXHIBIT 2-2

SITE INVESTIGATION AREA--SLOP

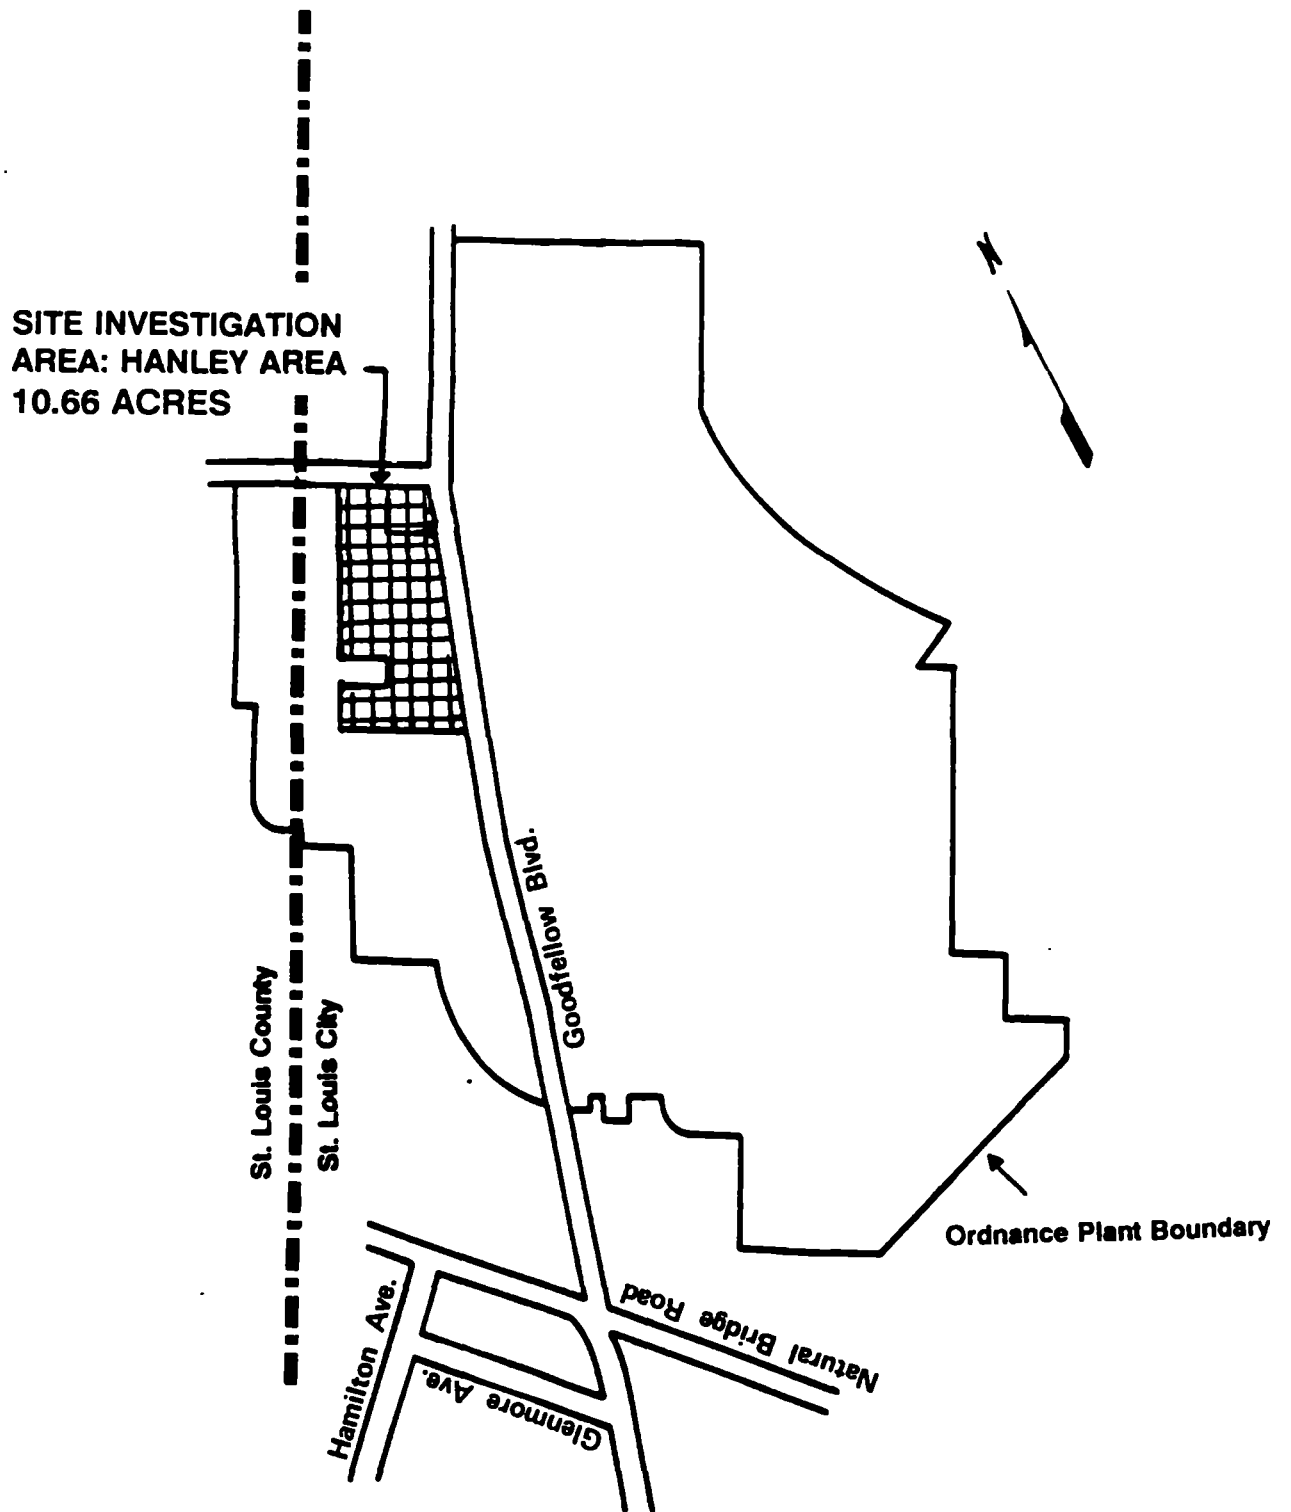

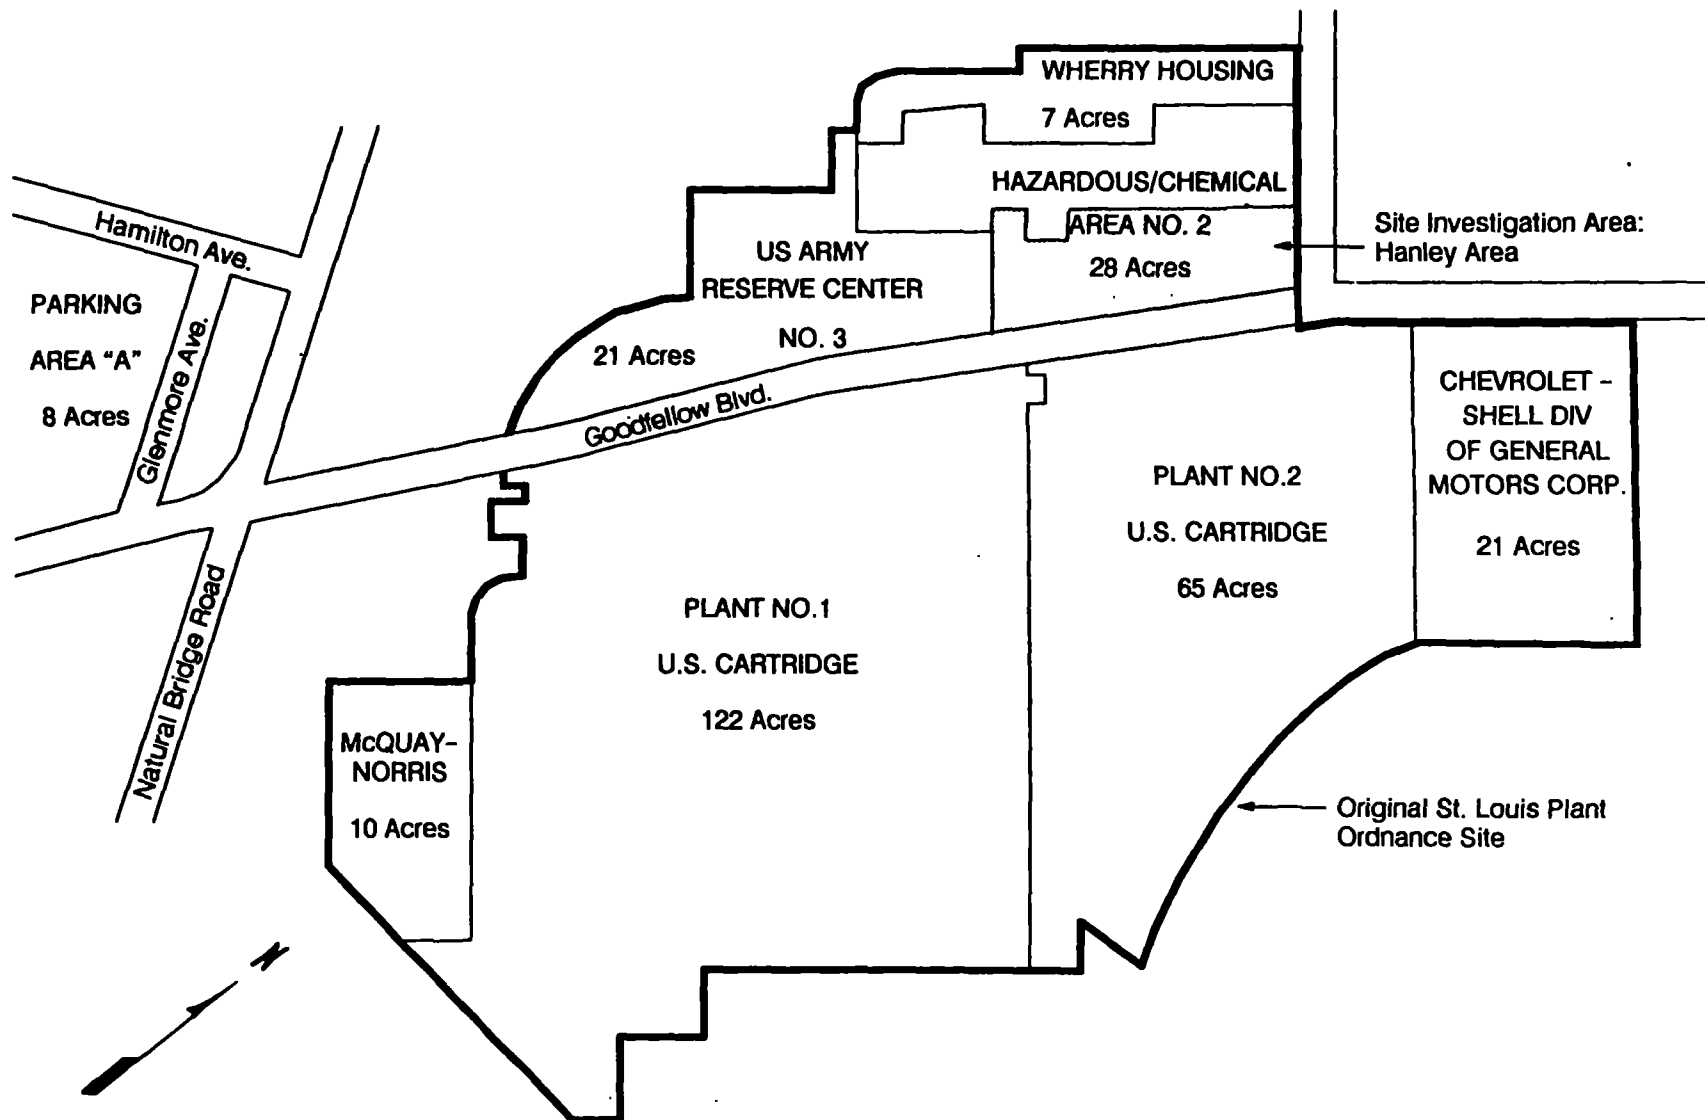

EXHIBIT 2-3

OUTLEASE MAP OF ST. LOUIS ORDNANCE PLANT

| | |
|--------------|---|
| | <ul style="list-style-type: none"> • The McQuay-Norris Manufacturing Company manufactured cores for small arms ammunition in a 10-acre area located to the extreme south of the installation, south of Interstate-70 on Goodfellow Boulevard near Natural Bridge Road (Exhibit 2-3). This company is reported to have produced 8 billion cores. • The Chevrolet-Shell Division of General Motors Corporation manufactured 105mm shells in a 21-acre plant, located in the northeastern part of the installation (Exhibit 2-3). This area was operated as the St. Louis Army Ammunition Plant (SLAAP). |
| 1945 | In 1945, SLOP was deactivated following the end of World War II. The U.S. Army Corps of Engineers (USACE) reportedly decontaminated all buildings having explosive contamination. Although no documentation of the decontamination procedures has been found, many buildings at SLOP bear markings of XXX, signifying 99.9% clean. This mark is used typically to indicate decontamination and inspection following decontamination to verify safety and absence of explosives contamination. With the exception of the powder wells that exist onsite, buildings and magazines located throughout the Hanley Area are so marked. |
| 1945-1951 | Following deactivation of the plant, an administrative center for the Army Service Forces, called the St. Louis Administration Center, occupied all property and buildings except the facilities used by McQuay-Norris. Installation buildings were used for maintaining and servicing records. During this period, the U.S. Army built the Wherry Housing Project, consisting of 120 apartments. This housing area is located west of the Hanley Area (Exhibit 2-3). |
| 1951-1957 | In 1951, the U.S. Army reactivated operations at SLOP in response to escalation of the Korean Conflict. The three previous contractors mobilized production of ammunition, cores and shells in the same areas of the installation previously used. In 1954, the U.S. Army placed the SLOP facilities producing shells (Chevrolet-Shell Division) on standby status. Small arms ammunition (U.S. Cartridge) and small arms ammunition core (McQuay-Norris) production continued until 1957 when the U.S. Army again deactivated SLOP. |
| 1957-Present | Little information has been found on facility operations on the facilities located in the east side of Goodfellow Boulevard for this time period. Between 1966 and 1969, the Army reactivated the Chevrolet-Shell plant area, for the production of projectiles. These areas are located beyond the boundaries of the Hanley Area, and most have since been excessed and transferred to a variety of federal and city government agencies, including the General Services Administration (GSA). The area to the west of the Hanley Area was used by the Goodfellow U.S. Army Reserve Center (GUSARC) and is currently the site of a Department of Labor Job Corps Center. |
| 1976 | The US Army Reserve established a new Reserve Center that abuts the southern side of the Hanley Area on the west side of Goodfellow Boulevard. This facility consists of an administrative building, a vehicle maintenance shop, and a large open area immediately adjacent to the Hanley Area that is used as a helicopter landing area. |
| Present | In addition to the Reserve Center, the Job Corps Center, and the GSA buildings, other commercial, residential, and industrial areas currently exist in the vicinity of the Hanley Area. |

2.1.2 Chronology of Operations - Hanley Area

Exhibit 3-2 (located in pocket B) depicts a site map of the Hanley Area and provides building numbers and locations that relate to the following discussion of site operations.

- 1941-1959** All discussion of activities prior to 1959 in the available reports encompass the entire 28 acres of Hazardous/Chemical Area No. 2 rather than providing any specific reference to the Hanley Area parcel. The history of activities occurring in the Hazardous/Chemical Area No. 2, prior to 1959 that may relate to the Hanley Area is summarized in this section. Activities during World War II include tracer bullet manufacture, primer manufacture, and explosive mixing and storage. In 1945, the USACE reportedly deactivated all buildings having explosives contamination. Following decontamination, the U.S. Army Finance Center used some buildings for classrooms. The Army reactivated the Area for small arms ammunition in response to the Korean Conflict. Although the Army installed machinery, production never commenced, and after the conflict, the Army removed and disposed of the machinery.
- 1959-1979** In 1959, Hanley Industries Inc. leased 14.7 acres of the Hazardous/Chemical Area No. 2; this area has since been known as the Hanley Area and is shown in Exhibit 2-4. Hanley Industries (Hanley) used the site for research, development, manufacture, and testing of various explosives and performed work in the design of explosive trains and components. Exhibit 2-5 lists explosive trains and components designed by Hanley, and operations occurring in the area included equipment for synthesis, receiving, drying, screening, mixing, loading, pressing, and testing of explosives. Additionally, Hanley loaded explosives into various component parts for both military ordnance and non-ordnance items. A list of items is given in Exhibit 2-6. Hanley used most of the buildings to load detonators, primers, and to mix explosives. Explosives were dried in magazines by leaving cans of explosives exposed to the air, and a lead azide reactor was operated in one of the magazines (exact location unknown). Reportedly, Hanley did not use the existing sumps or powder wells located on the property for wastewater disposal. Exhibits 2-7 and 2-8 provide summaries of the only information available on the uses of individual buildings in the Hanley area. Exhibit 2-9 provides a list of compounds utilized by Hanley Industries.
- 1979** The Army required Hanley to conduct decontamination of buildings as part of the lease termination. The decontamination procedures were not well documented, but apparently consisted of spray-washing of the walls in the buildings to a height of 8 feet above the floor. None of the magazines were spray-washed. Washdown wastewater from the cleaning operation was discharged onto the ground outside the buildings.
- 1979-** The Department of Labor expanded beyond the former Goodfellow USA Reserve Center and with a view toward using the Hanley Area, demolished some of the bunkers. The following buildings and associated concrete barricade walls have been demolished and there is no visible evidence of their existence: 226 A to H, 228 N to S, 227 - T and 229 H, J, K, L, M, and N. The action to use more of the Hanley Area has stopped and DOL/Job Corps is using an area of 17.1 acres. As a result, the inactive remains of the Hanley Area has been reduced to 10.66 acres. No operations have been conducted in the Hanley Area since the withdrawal by Hanley Industries in 1979. The inactive status of the area has resulted in seriously degraded and vandalized facilities. The Army has fenced off the area to prevent public access.

COMPOUNDS USED AT HANLEY AREA

Compounds

- Lead Styphnate
- Tetryl (2,4,6-Trinitrophenylmethylnitramine)
- RDX
- NOL 130 (Primer mix having the following composition:
 - 20% lead azide,
 - 15% antimony sulfide, 20% barium nitrate, 40% lead styphnate, and 5% tetracene.)
- Al80 (Ignition mix)
- Black Powder
- HMX (Cyclotetramethylenetetranitramine)
- NOL 60 (Primer mix having the following composition:
 - 10% antimony sulfide, 25% barium nitrate, 60% lead styphnate, and 5% tetracene.)
- PETN (Pentaerythrite Tetranitrate)
- Tetracene
- Silver azide
- Smokeless powder
- Trinitroresorcinol
- Diazodinitrophenol
- Delay powder (dependent on the composition used, may contain the following compounds:
 - barium chromate, zirconium powder, nickel powder, potassium perchlorate, red lead, silicon powder, lead chromate, and manganese powder.)
- Tracer mixes (dependent on the composition used, may contain the following compounds:
 - strontium peroxide, magnesium powder, barium peroxide, strontium nitrate, strontium oxalate, magnesium carbonate, and aluminum powder.)
- Lead nitrate
- Sodium azide

Future Future plans for the study area include renovation and use of existing buildings (Buildings 219G, 219D, and 219A) by the US Army Reserve Center. The Army Reserve has expressed an interest in repairing and renovating these buildings for use as warehouse space. If this occurs, only occasional and short-term occupancy of the buildings by authorized Army personnel likely will occur. The Army Reserve also has expressed an intention to maintain and control the remaining portion of the Hanley Area. Other future uses of this area likely would include demolition and removal of buildings (other than the warehouses).

2.2 SITE CHARACTERISTICS

This section provides a description and discussion of the physical characteristics of the site.

2.2.1 Site Description

The Hanley Area is located on a relatively flat terrace covering most of the 14.7 acres, and includes a steep slope down to Goodfellow Boulevard along the East side. A series of warehouse buildings, bunkers, and related buildings are located on the flat portion. The site contains a number of underground rooms, tunnels for service utilities, an underground wastewater collection system, and a stormwater collection system. A paved service road runs south-north along the east side of Buildings 219G, 219D, and 219A. The grounds at the site appear clean although the buildings show advanced signs of aging and neglect. A site map located in Pocket B (see Exhibit 3-2) shows details of the site layout for the Hanley Area.

All of the buildings present in the Hanley area have been stripped of equipment and this work, together with lack of maintenance, has left former production Buildings 218A, 218B, and 218C; warehouse Buildings 219A, 219D, 219G; and the frame buildings located inside the concrete-walled explosive containment bunkers in a state of poor repair. The massive concrete walls of the bunkers appear to be in relatively good condition.

A site drawing in Pocket A (see Exhibit 3-1) shows the underground tunnel system. The tunnels are constructed of reinforced concrete with approximate interior cross-sectional dimensions of 8 ft. wide x 8 ft. high, and connect to the basements of most of the buildings within the Hanley Area. The horizontal tunnels change elevation at abrupt intervals as required to maintain an elevation of 10-12 feet below the topographic surface. A stair-cased entrance or vent to the surface and a sump-like low area occurs at each point where the tunnel elevation changes. (One vent -- allowing access to the entire tunnel system - is located off-site along the east side of Goodfellow Boulevard. The tunnels have been blocked off between the Hanley Area and the area occupied by the Job Corps Center.) Other tunnel entrances exist in the basements of several buildings within the area. After large rain events, standing water occurs on the tunnel floors in low areas, principally within low areas where the tunnels change elevation.

The tunnels contain overhead pipes and pipe races along the tunnel walls, and many of these piping systems are covered with insulation. Utility pipes include water and steam. (One of the pipes -- obviously a water supply line -- was observed to be leaking during site visits in 1989 and 1990). The steam pipes are wrapped with asbestos-containing insulation, which shows signs of disrepair.

2.2.2 Physical Setting

The St. Louis Ordnance Plant is located on the western boundary of the city limits of St. Louis, Missouri and adjacent to St. Louis County. The facility lies approximately three miles west of the Mississippi River and 0.25 miles south of the intersection of Interstate 70 and Goodfellow Boulevard. (Exhibit 2-1).

The Hanley Area comprises 14.68 acres located within the 28-acre parcel formerly known as Hazardous Chemical Area No. 2. The Hanley Area is situated on a broad terrace with an elevation of approximately 550 feet above mean sea level. Surface runoff from the Hanley Area enters the city storm drainage system and flows eastward toward the Mississippi River. The topographic relief between SLOP and the Mississippi River to the east is approximately 150 feet.

Site Physiography

The St. Louis area is located on the northwestern flank of the Ozark Plateau in the Dissected Till Plains Physiographic Province (Exhibit 2-10). The St. Louis area has been a receiving basin for sediments for most of its geologic history. The stratigraphy of the geologic formations underlying this area are characterized as sedimentary formations. Hunt (1974) characterizes the Ozark Plateau as a broad uplifted area exposing early Paleozoic formations. Miller (1974) describes the Dissected Till Plain as a gently undulating surface with altitudes ranging from 500 to 700 feet. Glaciers covered the area twice during the Pleistocene. The study area lacks typical morainal topography of glaciated surfaces. Till deposits in the area are relatively thin.

Bedrock Geology

The bedrock geology of the St. Louis area consists of essentially flat-lying sedimentary rocks, mostly limestone and dolomite which were deposited in shallow epicontinental seas. The forces that produced the Ozark uplift controlled the regional structure of the rocks in the area. The apex of this activity forms the core of the St. Francois Mountains to the southwest (Howe, 1961). The St. Louis area has a monocline structure that gently dips to the northeast at an average rate of 55 feet per mile (Gleason, 1935).

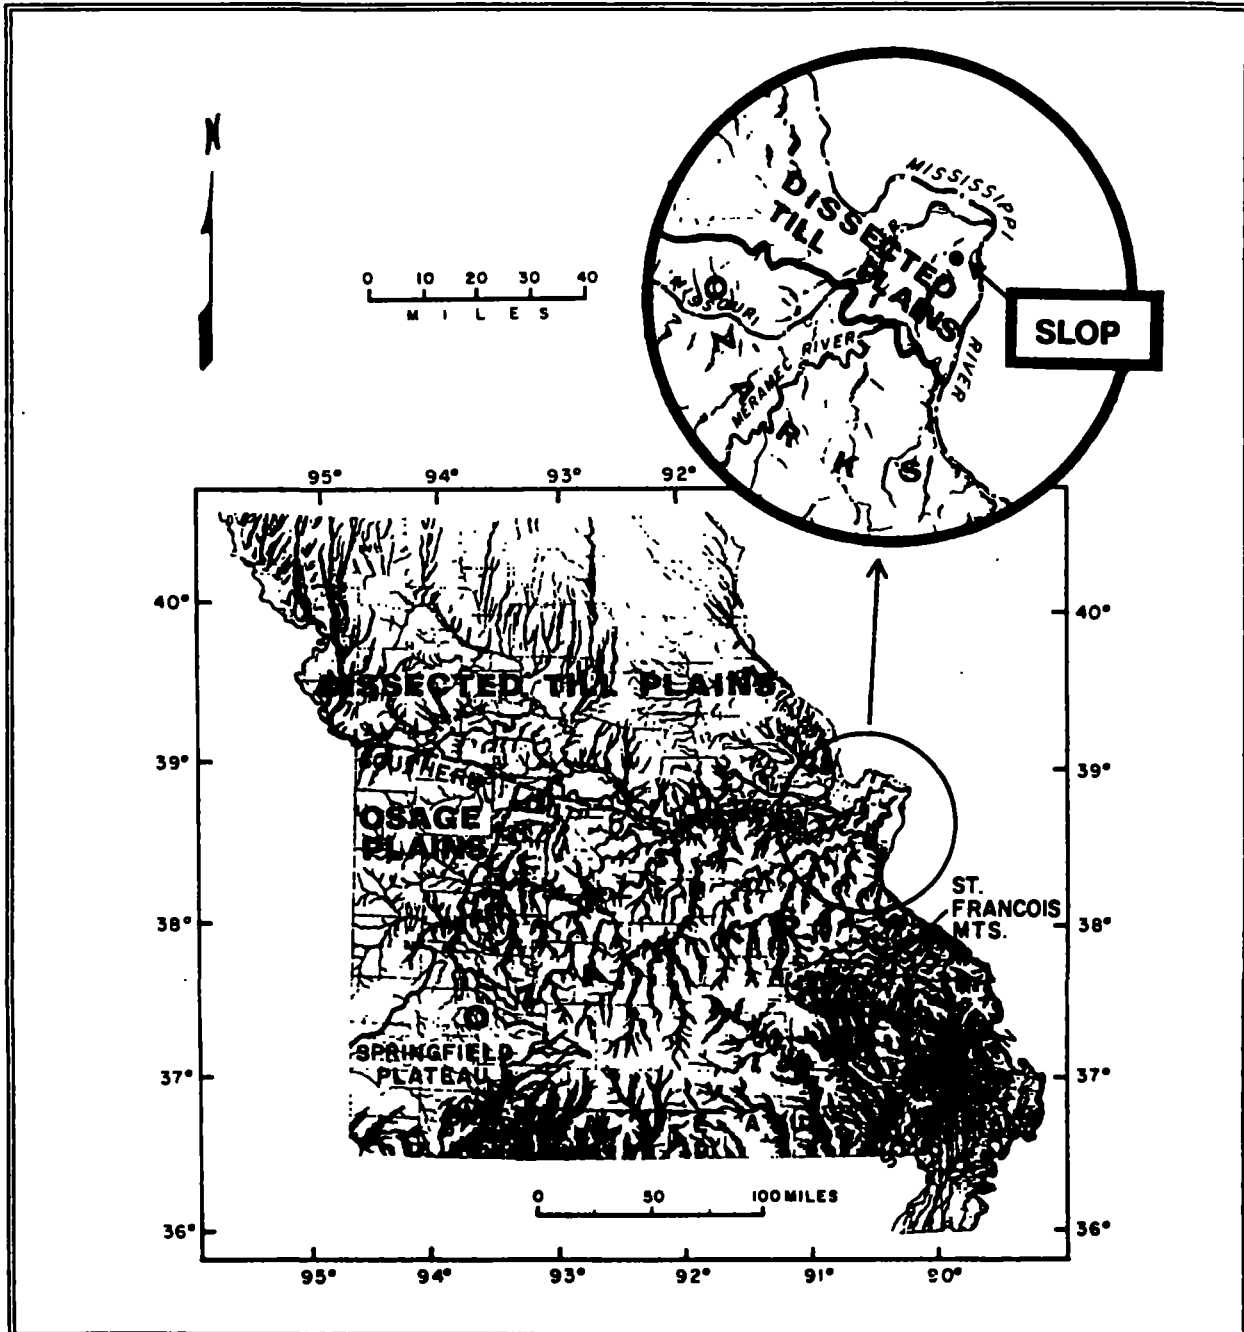

The structural attitude of the beds result from the compressional, tensional, and uplifting forces that have displaced and altered the beds from their original depositional positions (Miller, 1974). The combination of these forces have altered the beds so that presently a series of faults and fractures exist throughout the region. Locally, a number of faults are present both to the east and to the west of the Hanley Area of SLOP. Exhibit 2-11 illustrates the approximate locations of these faults and structural features.

The geologic formations in the St. Louis area range in age from Ordovician (430 million years before present (mybp)) to middle Pennsylvanian (300 mybp). Early Pennsylvanian age rocks of the Marmaton and Cherokee Groups make up the strata beneath the Hanley Area. Exhibit 2-12 presents a generalized stratigraphic column for St. Louis County, Missouri. These strata consist of mostly shale, but also contain thin, and not laterally continuous layers of clay, limestone, sandstone, and coal. Compared to the Cherokee group below, the Marmaton contains more limestone units which are thicker and more persistent (Howe, 1961). The Pennsylvanian units in the vicinity of SLOP have a thickness of less than 100 feet.

Mississippian age rock of the St. Louis and St. Genevieve Formations lie unconformably beneath Pennsylvanian strata. A gray lithographic to finely crystalline, medium to massively bedded limestone more than 100 feet thick characterizes the St. Louis formation (Howe, 1961). Thin shale beds are common, and in places the St. Louis formation is dolomitic. Howe (1961) describes the St. Genevieve formation as white, massively bedded, sandy, clastic limestone. It is generally coarsely crystalline and oolitic and contains a few beds of finely crystalline limestone. Additionally, the St. Genevieve may in

EXHIBIT 2-12

GENERALIZED STRATIGRAPHIC COLUMN FOR ST. LOUIS COUNTY, MISSOURI

| System | Series | Group | Formation | Aquifer Group | Thickness (feet) | Dominant Lithology | Water-bearing Character |
|---------------|---------------|-----------------|-----------------------------|---------------|------------------|--|--|
| Quaternary | Holocene | | Alluvium ¹ | | 0-150 | Sand, gravel, silt, and clay | Some wells yield more than 2,000 gpm. |
| | Pleistocene | | Loess Glacial till | | 0-110 0-55 | Silt Pebbly clay and silt | Essentially not water yielding. |
| Pennsylvanian | Missourian | Pleasanton | Undifferentiated | 1 | 0-75 | Shales, siltstones, "dirty" sandstones, coal beds and thin limestone beds | Generally yields very small quantities of water to wells. Yields range from 0-10 gpm. |
| | | Marmaton | Undifferentiated | | 0-90 | | |
| | Desmoinesian | Charokey | Undifferentiated | | 0-200 | | |
| | Atokan | | Undifferentiated | | | | |
| Mississippian | Meramecian | | St. Genevieve Formation | | 0-160 | Argillaceous to arenaceous limestone. | Yields small to moderate quantities of water to wells. Yields range from 5 to 50 gpm. Higher yields are reported for this interval locally. |
| | | | St. Louis Limestone | | 0-190 | | |
| | | | Salem Formation | | 0-180 | | |
| | | | Warsaw Formation | | 0-110 | | |
| | Osagean | | Burlington-Keokuk Limestone | | 0-240 | Cherty limestone | |
| | | | Fern Glen Formation | | 0-105 | Red limestone and shale. | |
| | Kinderhookian | Chouteau | Undifferentiated | | ~122 | Limestone, dolomitic limestone, shale, and siltstone. | |
| | | | | | | | |
| Devonian | Upper | Sulphur Springs | Bushberg Sandstone | | 0-80 | Limestone and sandstone | |
| | | | Glen Park Limestone | | | | |
| | | | Grassy Creek Shale | | 0-50 | Fossils, carbonaceous shale. | |
| Silurian | | | Undifferentiated | | 0-200 | Cherty limestone | |
| Ordovician | Cincinnatian | | Maquoketa Shale | 2 | 0-163 | Silty, calcareous or dolomitic shale. | Probably constitutes a confining influence on water movement. |
| | | | Cape Limestone | | 0-5 | Argillaceous limestone. | Yields small to moderate quantities of water to wells. Yields range from 3 to 50 gpm. Decorah Formation probably acts as a confining bed locally. |
| | Champlainian | | Kimmswick Formation | | 0-145 | Massive limestone | |
| | | | Decorah Formation | | 0-50 | Shale with interbedded limestone. | |
| | | | Plattin Formation | | 0-240 | Finely crystalline limestone. | |
| | | | Rock Ledge Formation | | 0-83 | Dolomite and limestone, some shale. | |
| | | | Joachim Dolomite | | 0-135 | Primarily argillaceous dolomite. | |
| | | | St. Peter Sandstone | | 0-160 | Silty sandstone, cherty limestone grading upward into quartzose sandstone. | Yields moderate quantities of water to wells. Yields range from 10-140 gpm. |
| | | | Everton Formation | | 0-130 | | |
| | Canadian | | Powell Dolomite | 4 | 0-150 | Sandy and cherty dolomites and sandstone. | Yields small to large quantities of water to wells. Yields range from 10 to 300 gpm. Upper part of aquifer group yields only small amount of water to wells. |
| | | | Cotter Dolomite | | 0-320 | | |
| | | | Jefferson City Dolomite | | 0-225 | | |
| | | | Roubidoux Formation | | 0-177 | | |
| | | | Gasconade Dolomite | | 0-280 | | |
| | | | Gunter Sandstone Member | | | | |
| Cambrian | Upper | | Eminence Dolomite | 5 | 0-172 | Cherty dolomites, siltstones, sandstone, and shale. | Yields moderate to large quantities of water to wells. Yields range from 10 to 400 gpm. |
| | | | Potosi Dolomite | | 0-325 | | |
| | | Elvina | Derby-Doerun Dolomite | | 0-165 | | |
| | | | Davis Formation | | 0-150 | | |
| | | | Bonneferris Formation | | 245-365 | | |
| | | | Lamotte Sandstone | | 235+ | | |
| Precambrian | | | | | | Igneous and metamorphic rocks. | Does not yield water to wells in this area. |

¹ Basal part may be of Pleistocene age.

NOTE: Stratigraphic nomenclature may not necessarily be that of the U.S. Geological Survey.

From: Miller, D.E., et al., 1974, Water Resources of the St. Louis Area, Missouri: Missouri Geological Survey and Waste Resources, WR. 30.

places contain lenses of chert and sandstone. In St. Louis County, the formation is approximately 30 feet thick. A disconformable contact exists between the St. Louis and the overlying St. Genevieve, with a basal conglomerate present in places.

A literature review and information gathered from borings in the vicinity of the SLOP facility indicates that bedrock occurs at a depth of approximately 20-30 feet beneath the ground surface. Bedrock at SLOP lies beneath unconsolidated sediments of the Harvester Complex, a characteristically moist sediment that lacks significant amounts of water. The bedrock contains Pennsylvanian age shales and clayey shales of Cherokee Group. These units are expected to be approximately 70 feet thick. Exhibit 2-13 presents a geologic map of the study area.

Almost all bedrock formations in the St. Louis region were covered by laterally extensive deposits of windblown silt (loess) derived from the floodplain of the Missouri River during the Pleistocene glaciation. Vertically, the area's loess deposits are relatively thin.

Climate

The climate in St. Louis County is characteristic of temperate continental, with warm-to-hot summers and cool winters. The heaviest rains occur in spring and early summer, when moist air from the Gulf of Mexico interacts with drier continental air (Soil Conservation Service, 1979).

The daily temperature for the St. Louis area averages about 55 degrees Fahrenheit (°F). The temperature averages about 33°F in winter, and about 77°F in the summer. The growing season for most crops extends from April to September.

Total annual precipitation is 33.8 inches, with the greatest amount falling in June. Average seasonal snowfall for the region is 18 inches, with most accumulation occurring in March. Wind prevails from the south. Wind speed is highest in March, averaging 12 miles per hour.

Soils

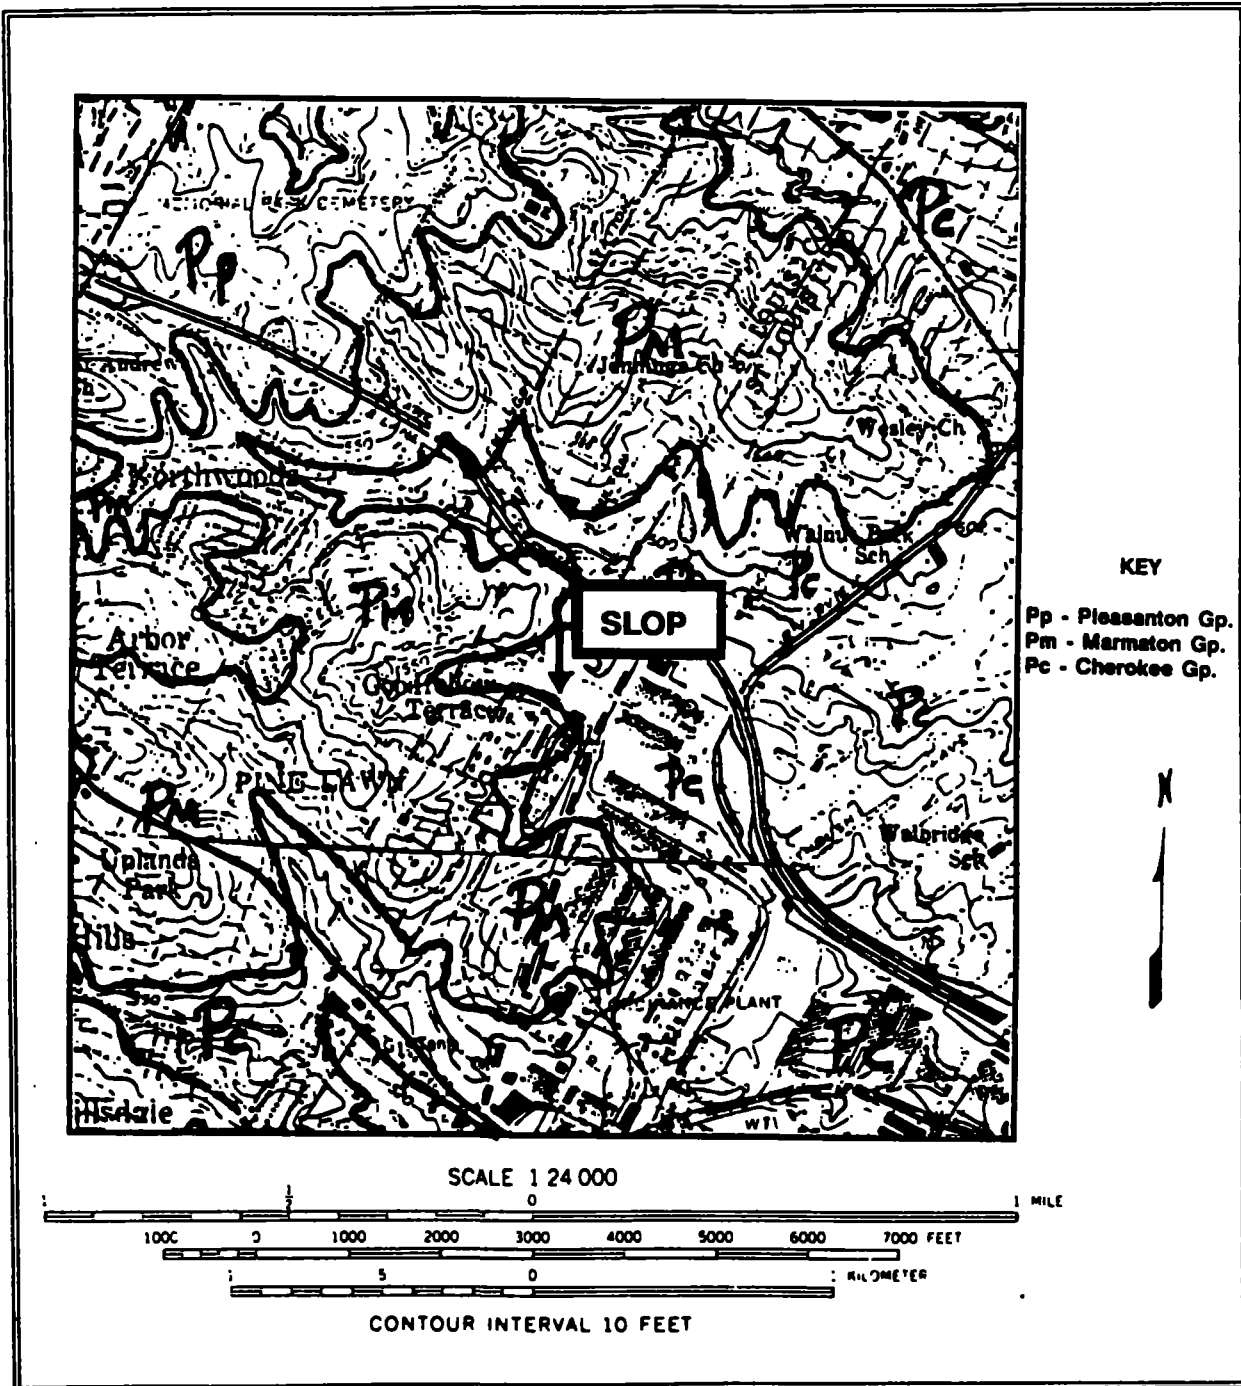

The soil matrix at the Hanley Area of SLOP has been characterized and mapped by the Soil Conservation Service (SCS) as Urban Land, upland, with 0 to 5 percent slopes. SCS describes this classification as surfaces composed of greater than 85 percent manmade, impervious materials. Typically, these soils have been extensively reworked and reshaped. Many construction activities at the facility leveled much of the site's original topography. The SCS has not performed detailed on-site investigation and classification of the soils in the Hanley Area due to the lack of access to the site.

Immediately adjacent to the contour boundaries of the Urban Land map unit, in all directions, lies the Urban Land-Harvester Complex. Harvester soils consist of deep, moderately drained soils on uplands. These soils were formed in 12 to 40 inches of reworked loess fill material over truncated or buried loess soils. These soils have moderately slow permeability.

Typically, the surface layer of the Harvester soil consists of about 4 inches of brown silt loam. The next layer, to a depth of approximately 37 inches consists of multicolored silt loam material that contains fragments of bricks, glass, cinders, and other manmade materials. The lower part of a buried soil remains below the reworked fill material, to a depth of approximately 60 inches. It is a dark yellowish brown, mottled, firm, silty, clay, loam. At heavily reworked areas, most or all of the original soil has been removed.

EXHIBIT 2-13

GEOLOGIC MAP OF THE STUDY AREA

From: State of Missouri, Geological Survey and Water Resources (Preliminary, not field checked).

Hydrogeology

Groundwater in the vicinity of the Hanley Area occurs primarily in fractures, solution cavities, and along bedding planes of the Mississippian limestone strata that lie beneath the younger Pennsylvanian rocks at SLOP. Generally, the Pennsylvanian shales of the area are relatively impermeable, and yield very little water. However, the Cherokee Formation is an exception which may contain small amounts of groundwater in the thin sandy shales and sandstone units that comprise this formation (Gleason, 1935).

It is expected that groundwater at the Hanley Area could be encountered at a depth of approximately 80 to 120 feet beneath the surface, at the base of the Pennsylvanian strata. Additionally, it is likely that one or more perched systems exist within the Pennsylvanian formations, although these systems are expected to be quite thin and very poor producers (Exhibit 2-14). Groundwater wells in the St. Louis area (Mississippian rock units) are classified as low producers with an average yield of less than 50 gallons per minute.

2.3 PREVIOUS INVESTIGATION

2.3.1 Overview

A site investigation was conducted for USATHAMA by Battelle Columbus Laboratories in 1979 when the Department of Labor identified the Hazardous/Chemical Area No. 2 as a potential site for placement of the Jobs Corps Center. The Battelle study encompassed both the Hanley Area and the former GUSARC area (currently the site of the Job Corp Training Center). The purpose of the investigation was to ascertain whether residues remained after previous decontamination efforts, and the suitability of the property for release to the Department of Labor.

Battelle conducted the investigation in two phases. The GUSARC area investigation occurred from January-May of 1979, and the Hanley Area investigation occurred from August-November of 1980. Battelle's survey efforts included a site survey and visual inspection, and selected field sampling for heavy metals and explosives contamination. In June, 1981, USATHAMA released a report containing the results of these surveys and additional information on historical use of the property.

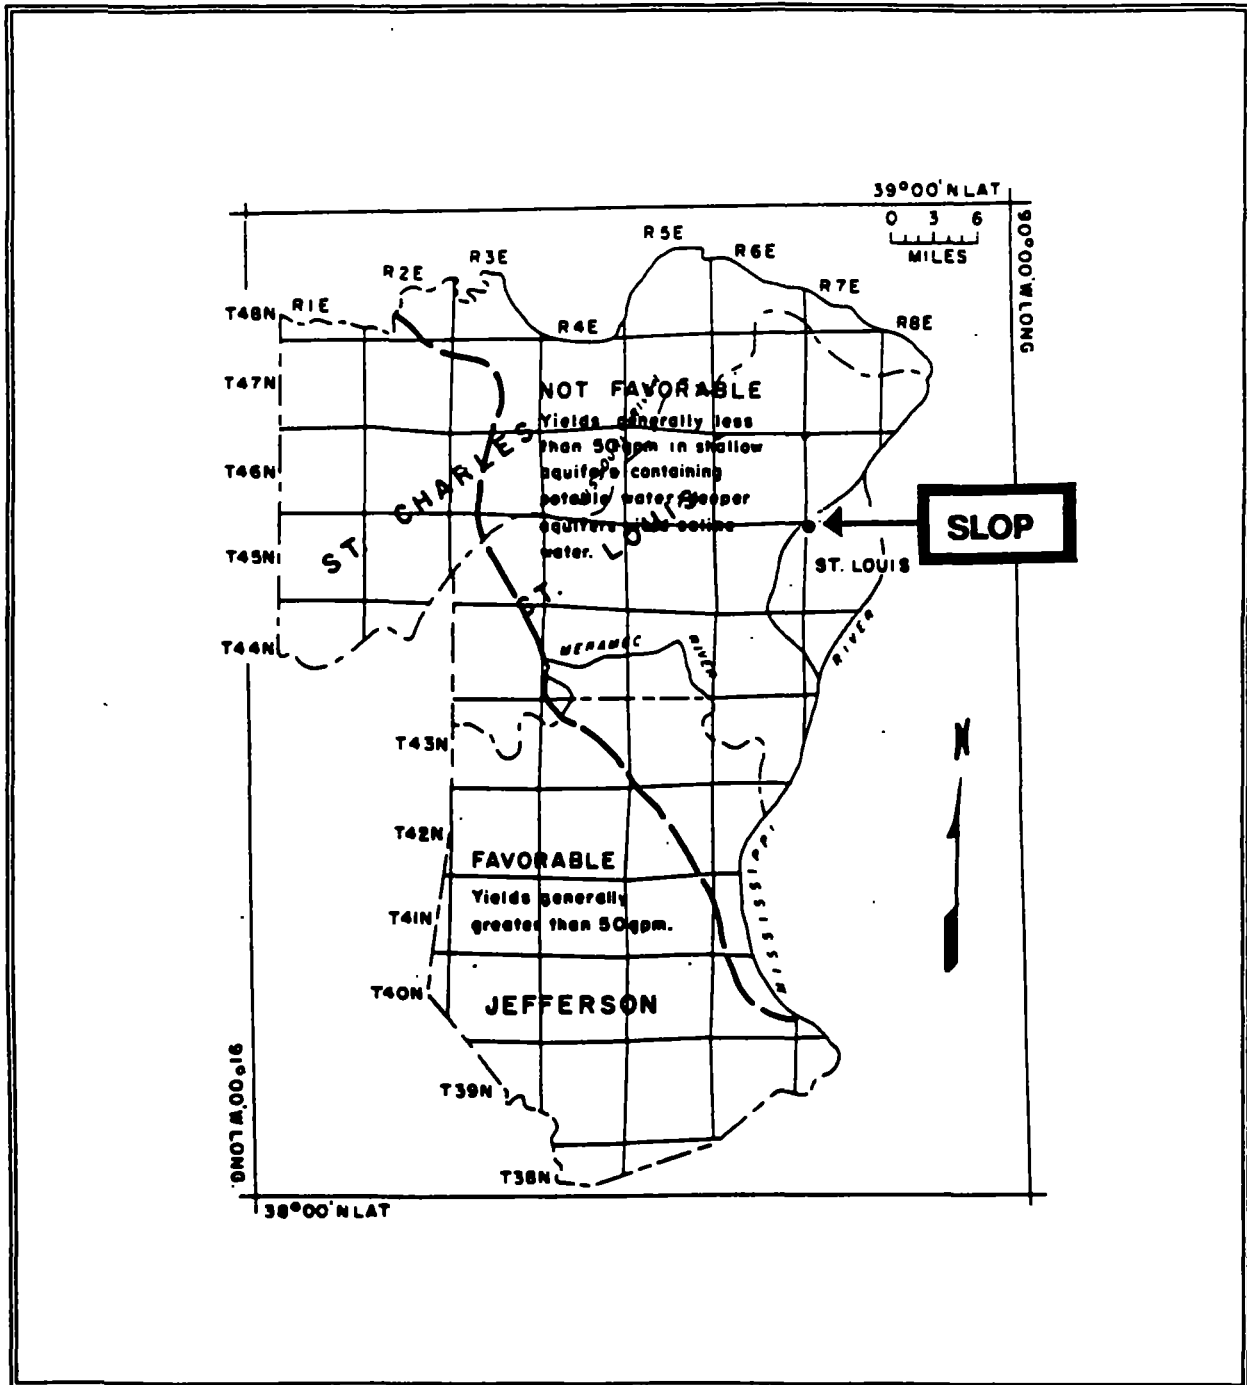

2.3.2 Historical Investigation

The historical investigation consisted of a records search and interviews with current and former employees. The records review included searching the National Personnel Records Center, St. Louis, MO; Industrial Social Division of the National Archives, Washington, DC; Washington National Records Center, Suitland, MD; Offices of the Kansas City District Corps of Engineers, Kansas City, MO; and the Historical Office of the Army Armament Readiness Command, Rock Island, IL. Documents specific to building and magazine usage and site decontamination were not located.

Exhibit 2-15 summarizes information on site operations in the Hanley Area from Hanley employees and the records review. Exhibit 3-2 (Pocket B) provides a map showing the locations of the buildings and related structures. Hanley reportedly did not use the powder wells for wastewater disposal, but used some of the on-site magazines for storage of explosives and other materials and used several of the buildings for munitions production and storage activities. All explosive wastes generated by Hanley were reported to have been transported to Ft. Leonard Wood for disposal (USATHAMA, 1981).

EXHIBIT 2-14

YIELDS FROM BEDROCK AQUIFERS

From: Miller, D.E., et al., 1974, Water Resources of the St. Louis Area, Missouri: Missouri Geological Survey and Water Resources, WR. 30.

2.3.3 Visual Survey

A visual survey of the grounds, buildings, and tunnels in 1980 located several detonators that have since been removed. Inspection of the buildings in the Hanley Area indicated that in several cases interior building walls were constructed of hollow tile in which explosive residues could have accumulated. It is not known whether samples from these areas have been analyzed for explosives.

2.3.4 Results of Prior Investigations

Sampling and analysis activities in the Hanley Area were initiated in August 1980, shortly after Hanley personnel reportedly completed decontamination procedures. Field activities included the sampling of seven buildings, 54 magazines, five sewer pipe locations and the contents of 28 powder wells. Samples were analyzed for heavy metal and explosive residues. Surface spot-spray screening and swab samples were used to locate contamination from explosives residuals, and wipe samples were collected from surfaces in each of the buildings and magazines for metals analysis. Samples from a given area were composited and analyzed by atomic absorption spectroscopy for lead, silver, nickel, mercury, chromium, and cadmium.

The results of the 1980 survey indicate that areas of potential contamination include building surfaces, powder wells, sewers, and other structures associated with munitions production, packing, or storage activities. Contaminants found include both explosive residues and heavy metals.

Building Survey

Building swipe surveys for selected metals were conducted by compositing swab samples obtained from the floor, walls, and baseboard surfaces of each building. The results of these metal analyses generally agree with the historical building usage (e.g., sources of metals associated with primer and tracer mixing operations using metal-based compounds). Concentrations of chromium in building swipe surveys ranged from 26 to 515 $\mu\text{g}/\text{m}^2$. The maximum chromium concentration was found in Building 228E. Lead concentrations ranged from 800 to 27,200 $\mu\text{g}/\text{m}^2$. The maximum lead concentration was found in Magazine 219C, which records indicate was the location of a Hanley lead azide reactor. Exhibit 2-16 provides a map that shows buildings/magazines where metal contamination was found above detection limits. Exhibit 2-17 provides tabular data on the results of the metals survey.

Sampling of the buildings and magazines for explosives contamination involved two methods. A screening survey was performed by use of spot sprays containing reagents that provide color responses in the presence of certain explosive compounds. Surfaces of walls, vents, pipes, drains, window sills, ceiling fixtures, machinery, shelves, and floors where contamination may have collected were surveyed in this manner. Swab samples were then collected near each location where spot sprays generated positive results. These samples were composited by magazine group or individual building for laboratory chemical analysis.

Samples also were collected from the "powder well" sumps which accumulated drainage from many of the buildings and which reportedly had not been decontaminated. One-liter samples from each of the 28 powder wells were collected and composited into 9 samples according to building or magazine group. Samples were analyzed for explosive constituents.

Several buildings/magazines exhibited contamination from explosive residues. Positive results were obtained from spot spraying and verified by laboratory analyses in buildings and magazines labeled 218A, 218B, 218C, 219C, 219H, 220, 227A, 227B, 227J, 227M, 227O, 228C, and 228F. Explosive compounds were not detected in any of the powder well samples except those receiving effluent from

²M=mid.

Buildings 218A and 218B, which contained 4.0 and 4.6 ppb of tetryl, respectively. Explosives contamination results also generally agree with historical building usage. Exhibit 2-18 provides a map showing structures at the Hanley area where explosive contamination was found above detection limits, and Exhibit 2-19 lists the analytical data for these buildings.

Sewer Survey

Samples of water at five sewer locations in the Hanley Area were collected for explosives and metals analysis. The sewers at these locations drained powder wells, buildings, and magazines for both the Hanley and the GUSARC Areas. No concentrations above the detection limits were found for silver, mercury, and chromium. Lead concentrations ranged from below detection limit (bdl) to 230 µg/L and nickel concentrations ranged from bdl to 115 µg/L. None of the sewer samples exhibited concentrations of explosives above detection limits. Although the sampled sewer lines were indicated on a map, exact correlation of results to sewer location was not possible.

The investigative effort conducted in the adjacent GUSARC area also entailed wipe sampling of interior surfaces of buildings (total of 41), bunkers (7), and multiple-chamber powder sumps (9) for heavy metals and explosives contamination. Wipe samples, sludge, dust, and water samples were collected. Heavy metals residues were found to be present on the interior walls of most of the GUSARC buildings and bunkers. Contamination from explosives was found in the floor drains of several buildings.

⁴Powder well samples were composited from the powder wells existing outside buildings 218A and 218B, respectively.

3.0 CURRENT SITE INVESTIGATIONS

Previous studies have shown that building surfaces and waste handling system components contain explosives and metal residues associated with prior use of the facilities. However, the available data was insufficient to evaluate the potential for adverse impacts and to determine cleanup requirements. The present study was performed to provide supplemental data on the nature and extent of contaminated media and structures within the Hanley Area, specifically related to determining the need for remedial measures. Sampling was planned to quantify potential contamination in soil and groundwater, and within the tunnel system. Field sampling activities are described in the following sections and are summarized as follows:

- A screening survey was performed and samples collected to determine the extent of ACM within the buildings and tunnel system;
- Soil samples were collected across the site to evaluate the presence of contamination potentially affecting surface runoff and groundwater; and
- Samples were collected from standing water within the tunnel system (the only surface water source present at the site) as an indicator of whether off-site migration via surface routes is occurring. No substantial sediment deposits were encountered within the concrete tunnels.

A second phase of the study was planned to install four groundwater monitoring wells if the results of the soil and tunnel sampling indicated a significant potential for groundwater contamination.

No problems were encountered in sampling and analysis activities associated with the ACM survey. However, problems with data validation occurred with samples collected for chemical characterization of soils and tunnel water. The initial samples were collected in June, 1989, and submitted to a laboratory selected by USATHAMA for explosives and metals analysis. Considerable difficulties were encountered in obtaining results from the laboratory and, when preliminary data were made available in January, 1990, serious questions were raised about analytical validity both by USATHAMA and ICF KE quality assurance personnel. After thorough review, questions remained about the integrity of the laboratory results, and the analytical data from this initial sampling was declared invalid in July, 1990. In September, 1990, ICF KE collected a second set of soil and water samples which were analyzed without incident by a different USATHAMA-certified laboratory. The description of sampling activities given below addresses only the second sampling event.

Considerable changes have occurred at the site since the second sampling event, especially with respect to the tunnel system and a transformer at the site identified as having contained PCBs. It is the intent of this report to explain what was observed in July, 1990 as well as documenting events that have occurred since then which have served to improve environmental conditions at the site.

3.1 BUILDING AND TUNNEL ASBESTOS SURVEY AND SAMPLING

A screening survey was performed to determine the prevalence of ACM in the Hanley Area and the magnitude of problems these materials would pose for future remedial measures at the site. The survey and bulk sampling performed was not intended to be comprehensive in nature during this initial asbestos location survey.

The ACM survey was conducted in the Hanley Area during the period of June 28-30, 1989. The survey entailed evaluating the presence of ACM in all above-ground buildings, indoor and outdoor utility

pipes, and subterranean spaces (tunnels, crawl spaces, and basements). All piping and structures potentially containing asbestos were visually inspected, traced and color-coded, and samples were collected from each representative matrix. Eleven samples were submitted to CETCO Laboratory in Weymouth, MA, for analysis by polarized light microscopy in combination with dispersion staining techniques (PLM-DS) to identify whether asbestos was present and the type and approximate amount of major constituents.¹

Samples for ACM analysis were collected using standard protocols that minimize the potential introduction of asbestos fibers into ambient air. Each sampling location was wetted liberally with water prior to sample collection, and the damaged area was repaired and covered with adhesive plastic tape. For insulation materials, an entire cross section was sampled with a cork-boring tool, whereas samples of roofing and floor materials were simply torn or broken off. Each sample was placed in a 50-mm covered petri dish, labeled, and sealed inside a polyethylene bag for shipment to the laboratory.

The locations of samples collected for asbestos analysis are shown in Exhibit 3-1 (see Pocket A). Sample identification and a description of sampling locations are provided with the analytical results in Section 6.

3.2 TUNNEL SYSTEM WATER SAMPLING

Standing water within the tunnel system was collected at two locations. Samples were obtained near the point where each major branch of the tunnel system exits the Hanley Area, from the sump-like collection basin that exists at the lower level of elevation changes in the tunnel floor. The tunnel sampling sites are located on the extreme eastern and northern portions of the tunnel system. Samples of the standing water were analyzed for the Target Analyte List (TAL) of inorganic contaminants, explosives, and the Target Compound List (TCL) of organic constituents. Exhibit 3-2 (Pocket B) shows the location of samples collected from the tunnels.

Protocols approved by USATHAMA were used to collect the water samples from the underground tunnel system. Prior to sampling, all sampling equipment was thoroughly cleaned with USATHAMA-approved deionized water. The pH, conductivity, and temperature at each location was measured and recorded in a bound logbook, along with the total depth of standing water, time of sampling, and any other observations. All samples were collected by submerging the appropriate sample container (cleaned according to USATHAMA protocols) into the standing water, in such a manner that disturbance of the water surface was minimized. Sample containers and caps were triple-rinsed with the sample water prior to filling.

Samples were collected in order of decreasing volatility, with samples to be analyzed for volatile organic constituents (VOCs) collected first into 60 mL amber glass vials with screw caps and septa. Semivolatile organic/explosives samples were collected in 1-liter wide-mouth amber glass bottles with Teflon-lined lids. Samples for metal analysis were collected into 1-liter plastic cubitainers, and preserved with nitric acid to a pH \leq 2. Samples for cyanide analyses were collected in 1-liter plastic cubitainers, and

¹Since the ICF KE survey, personnel from the Directorate of Engineering and Housing, Ft. Leonard Wood collected 34 additional samples in October 1989 from warehouse Buildings 219A, 219D, and 219G. ECOSAFE Incorporated (Durham, NC) conducted the analysis of these samples.

preserved with sodium hydroxide to a pH \geq 12. After collection, samples were immediately placed in a sample cooler and maintained at 4°C. A trip blank for VOC analysis was sent with the aqueous samples. Sample custody and chain-of-custody were maintained throughout the field and laboratory effort.

3.3 SOIL SAMPLING

A total of 29 soil samples were obtained from 15 locations in and around the Hanley Area. Exhibit 3-2 (Pocket B) provides a map showing soil sampling locations. Sampling locations were selected based on known prior activities in the Hanley Area that may have contributed to on-site contamination; specifically, samples were collected at or near building openings where spills and sweepings from floors would have accumulated.

Considerable disturbance of the surface soils in the area has occurred due to brush clearance and reseeded work performed in 1989 and 1990. Therefore, soil samples were generally collected at each location from two depth intervals (0-1 ft and 1-2 ft). During the course of the sampling, an inoperable and leaking vintage electrical transformer was found in the area and a soil sample for PCB analysis was obtained from the soil surface beneath the leak. Of the other 28 soil samples, all were analyzed for selected metals and explosives. In addition, nine of the samples were analyzed for TAL/TCL constituents, and of those nine, four samples were also analyzed by the Toxicity Characteristic Leaching Procedure (TCLP) method. The more complete analyses were conducted on samples collected from the lower sampling depth.

A total of six soil samples were collected from three different background locations upgradient from the buildings in the Hanley Area, although within the original boundaries of SLOP. At each location, two samples were collected- one from a depth of zero to one foot and the second from a depth of one to two feet.

Soil samples collected for VOC analysis were collected by first making a boring to the appropriate depth using a shovel or bucket auger. A stainless steel scoopula was used to collect the sample, immediately placing it in a 120 mL amber glass bottle with a Teflon-lined cap. Care was taken to minimize the headspace within the sample bottle. The sample bottle threads were quickly wiped with a clean paper towel and the cap immediately tightened. Immediately after collection, samples were placed in the sample cooler and maintained at 4 °C. Chain-of-custody forms were completed and enclosed in the sample coolers.

Soil samples not intended for volatile organic analysis were collected by making a boring to the appropriate interval using a clean shovel or bucket auger and placing the excavated soil in a stainless steel pan. The sample was homogenized using a clean stainless steel trowel, then bottles were filled using a stainless steel scoopula. One sample for semivolatile constituents, metals, and explosives analysis was collected in a 500 mL amber glass sample bottle with Teflon lined caps. Traces of soil remaining on the sample bottle and threads were removed using a clean paper towel, the cap was immediately tightened, and the sample placed in a cooler at 4 °C.

Sampling equipment used to obtain soil samples was cleaned by scrubbing and rinsing with approved deionized water, then protected by wrapping with aluminum foil prior to use at the next sampling location. Two equipment rinsate blanks were collected following decontamination procedures to evaluate the effectiveness of these efforts to minimize sample cross-contamination.

All measurements and locational information regarding sampling activities were recorded in a permanently-bound logbook with numbered pages. Information recorded included: sample number; depth of sample; visual observations of sample including color, water content, and composition; date and

4.0 REGULATORY CRITERIA

This section provides an overview of regulatory criteria potentially applicable to an assessment of results from the SLOP investigation. Available criteria and guidance from the USEPA (EPA), the Missouri Department of Natural Resources (MDNR) and local regulations applicable to task objectives, site conditions and contaminants found at SLOP were evaluated.

4.1 ASBESTOS

Based upon the determination that asbestos emissions pose a serious risk to human health, EPA established regulations to reduce such risk. The State of Missouri adopted the National Emission Standards for Hazardous Air Pollutants (NESHAP) in regulating asbestos emissions. NESHAP defines asbestos containing material (ACM) as any material containing more than 1% by weight of any of the five mineral forms of asbestos. The definition describes friable ACM further as any ACM "that, when dry, can be crumbled, pulverized, or reduced to powder by hand pressure" (40 CFR 61.141). A November 20, 1990 federal ruling more specifically categorizes ACM and provides methods for asbestos analysis. The State of Missouri has not yet adopted this new ruling.

Demolition or renovation activities must follow NESHAP regulations in addition to State amendments. These requirements include removal or adequate wetting of all friable ACM or ACM which would become friable upon exposure during demolition (40 CFR 61.147(a)). In addition to notifying the Federal Administrator at least 10 days before abatement, facility owners within the St. Louis City limits must also notify city and state authorities at least 20 days prior to abatement activities and submit a \$100 filing fee. 40 CFR 61.145(b) provides specific information required for submission to federal authorities. (Removals involving less than 10 square feet or 16 linear feet of ACM do not require such notification.) Missouri requires that a state certified contractor perform any asbestos abatement. Further specifications concerning the procedures for asbestos emission control are given in 40 CFR 61.145(c).

The provisions of the Occupational Safety and Health Act (OSHA) provide protection to workers involved in the demolition or renovation of buildings containing ACM. OSHA regulations also address protection of Army personnel that may occupy buildings at SLOP containing ACM. OSHA mandates that an employer must ensure that certain exposure limits are not exceeded. This may require surveillance if the air reaches action levels of ACM. EPA and OSHA are currently working on new regulations to control asbestos in public and commercial buildings. At the time of this writing, no promulgation date had been issued.

4.2 WATER

Several federal regulations provide standards for water quality, none of which appear to be directly applicable to the situation at SLOP. Neither the Maximum Contaminant Levels (MCLs) available under the Safe Drinking Water Act (applicable to drinking water) nor the Ambient Water Quality Criteria contained in the Clean Water Act (applicable to potentially habitable ecosystems) relate directly to the standing water contained in the tunnels, and discharge limits have not been established through any permitting action. Therefore, the most applicable regulatory guidance appears to be standards developed for waters entering local sewer systems and/or directly discharged to the Mississippi River.

The Metropolitan St. Louis Sewer District (MLSD) effluent permit standards were used as a point of comparison for the tunnel water analytical results, not as a criteria for judging tunnel water quality. The effluent standards for selected metals are provided in Exhibit 4-1.

EXHIBIT 4-1

METROPOLITAN ST. LOUIS SEWER DISTRICT DISCHARGE CONCENTRATIONS
FOR SELECTED METALS

| METAL ANALYTE | METROPOLITAN ST. LOUIS SEWER DISTRICT DISCHARGE LIMIT ¹ (ppb-µg/L) |
|------------------|---|
| Lead, total | 200 |
| Aluminum, total | no limit exists |
| Barium, total | 10,000 |
| Chromium, total | 5,000 |
| Manganese, total | no limit exists |
| Sodium | no limit exists |
| Zinc, total | 3,000 |
| Copper, total | 1,500 |
| Iron | 15,000 |
| Magnesium | no limit exists |
| Calcium | no limit exists |

¹Metropolitan St. Louis Sewer District, Ordinance No. 4786.

4.3 SOIL

Standards have not been developed, either by EPA or MDNR, concerning the permissible concentration of contaminants in soil. Many of the metals found at SLOP, including lead, chromium, cadmium, and nickel, are classified as US EPA hazardous wastes and priority pollutants.

The MDNR evaluates clean-up action levels on a site-by-site basis. Cleanup action levels are established based on factors such as site-specific characteristics, potential for contaminant migration, and the potential of health impacts to the surrounding population (most strictly applicable to groundwater use).

The MDNR has not provided any guidance on action levels for pollutant concentrations found in SLOP soils, and soils data will need to be submitted to MDNR in order to obtain a regulatory assessment. Individuals at the Missouri Department of Health, the MDNR Waste Management Division, and at the MDNR Lab Services Division were contacted in an attempt to gather information on state agency policy on cleanup action levels and to ascertain actions that have previously been taken at other sites in Missouri contaminated with metals and organics. In addition, all Records of Decision (RODs) for previous Superfund activities in Missouri were reviewed to determine if cleanup levels were established for metals.

Guidance on potentially applicable cleanup levels also is available from a recently-published proposed EPA rule (as 40 CFR Parts 264, 265, 270, and 271) for concentrations meeting criteria for action levels in environmental media [Federal Register, July 27, 1990, p. 30798ff]. Proposed levels in soil for selected contaminants relevant to SLOP are shown in Exhibit 4-2. It is noted that the rule and levels given are strictly applicable only to RCRA Solid Waste Management Units and have not yet been adopted. However, the proposed concentrations have been used to evaluate the seriousness with which EPA may view contamination levels found in the soil at SLOP. It is also noted that no criterion for lead in soil has been provided.

One of the soil samples collected in the Hanley Area was obtained from beneath a leaking transformer. The regulations addressing polychlorinated biphenyls (PCBs) manufacturing, processing, distribution in commerce, and use prohibitions (40 CFR 761) define a "spill requiring cleanup action" as the intentional or unintentional spill, leak, or other uncontrolled discharge where release results in any quantity of PCBs running off or potentially running off equipment, or any resulting contamination. A spill requires cleanup if the PCB concentration is 50 ppm or higher (40 CFR 761.123(2)).

5.0 QUALITY ASSURANCE/QUALITY CONTROL

5.1 INTRODUCTION

A quality assurance program was implemented for SLOP to verify the integrity and reliability of activities associated with the generation of defensible environmental data. The quality assurance program encompassed thorough planning, explicit specification of data quality objectives, continual application of quality control measures to preclude out-of-control situations, and the establishment of monitoring systems to ensure the expeditious identification, evaluation, and correction of system deficiencies.

The quality assurance program for SLOP was implemented and maintained through use of well defined quality control protocols developed in conjunction with specifications contained in the USATHAMA guidance documents, *Installation Restoration Quality Assurance Program*, December 1985, 2nd Edition, March 1987 and the *Geotechnical Requirements for Drilling, Monitor Well, Data Acquisition, and Reports*. Other quality control criteria were based on ICF KΞ Standard Operating Procedures (SOPs).

The SLOP quality assurance program was maintained through adherence to SOPs, periodic monitoring of sampling and analysis systems, and frequent evaluation of data management activities. The following sections identify the quality assurance program established and maintained during the performance of the SLOP work assignment. Specific areas this section addresses include: data quality objectives in terms of accuracy, precision, completeness, comparability, and representativeness; field sampling and measurement protocols; field audits; analytical services; and blank contamination assessment.

5.1.1 Quality Control Criteria

The quality control criteria used to ensure the integrity of data generated in support of project activities included:

- **Project Planning and Site Characterization:** A site visit was conducted prior to development of the project work plan. The visit occurred in the Hanley Area of SLOP on April 11 and 12, 1989, to discern existing site conditions and to augment the available information on the installation. A site map was prepared as a result of the visit, which more accurately depicted the boundaries of the study area. Historical information was reviewed and evaluated to assist in the development of a sound site assessment program.
- **Project Work Plan:** The sampling design program for SLOP activities was developed using a phased approach. Phase I entailed an investigation of the surface soils in the study area to determine the nature and extent of surface soil contamination. During this phase, an asbestos-location survey was conducted in all building spaces and inside the tunnel system beneath the Hanley area. The sampling and analysis of free-standing liquids was also conducted for Phase I activities.

Phase II activities, which were planned to consist of subsurface soil and hydrogeologic investigations to discern the vertical and lateral extent of contamination, were not conducted under this Delivery Order.

- **Data Quality Objectives:** Data quality objectives were developed concurrently with the work plan to ensure that: (1) field sampling, chemical analyses, and physical analysis would be reliable; (2) sufficient data would be collected; (3) the quality of data generated

would be acceptable for its intended uses; and (4) valid assumptions could be inferred from the data.

- **Standard Operating Procedures:** Sampling activities were performed in compliance with criteria defined in the USATHAMA guidance documents for sampling events, as specified in SOPs. Chemical analyses were performed using USATHAMA-certified methodologies.
- **Sampling Personnel:** Field team members possessed the appropriate qualifications and training for the collection of representative samples. Each individual was experienced in the requisite protocols for collection of environmental samples and the performance of geology-related tasks. In addition, each team member was familiar with the SLOP work plan and the QA/QC information pertinent to field activities.
- **Documentation:** Field documentation was provided to the laboratory on forms developed specifically for USATHAMA investigations. The forms contained the requisite information for encoding chemical data into the Installation Restoration Data Management System. All entries into field logbooks were evaluated for completeness and accuracy.
- **Chain-of-Custody:** All samples were collected and relinquished under stringent chain-of-custody protocols as specified in the project quality control plan.
- **Document Control:** All documents generated in support of project activities were controlled by a document control system. A unique control number was assigned to each document prior to its being archived into the system. Access in the document control system was restricted to designated personnel.
- **Monitoring:** Audits were conducted to verify the integrity of work performed in support of this project, and to provide formal documentation attesting to the reliability of the audited system. Field audits were conducted at SLOP on June 27, 1989, when the first field sampling event occurred, and on September 25, 1990, during the followup field sampling event.
- **Analytical Services:** Chemical analyses were performed using USATHAMA-certified methodologies, as appropriate. The laboratory was responsible for ensuring the quality of data acquired during chemical analysis, and USATHAMA provided the data validation through the acceptance of quality control charts generated during chemical analysis. Optimal analytical performance by the laboratory was ensured through frequent evaluations of performance and system audits, preventive maintenance, and corrective action.

5.2 FIELD MEASUREMENT AND SAMPLING ASSESSMENT

The integrity of field sampling and measurement systems have been assessed through the data quality indicators, i.e., accuracy, precision, completeness, and representativeness. In addition, the results of field audits conducted at the site infer the level of accuracy, precision, completeness, and representativeness associated with sampling activities.

- **Accuracy:** Defined as the bias in a measurement system, sampling accuracy has been assessed through the evaluation of trip and rinse blank data. This information indicates whether contamination was introduced during the sampling event. A more detailed discussion is presented in the blank contamination assessment section.

The accuracy of field measurements for pH and conductivity for water quality criteria was inferred from the calibration logs generated before, during, and after analyses. The sampling crew adhered to the requisite protocols for the calibration of field equipment. Evidentiary documentation of this fact is contained on the requisite field parameter form.

- **Precision:** Precision is a quantitative measure of the variability of a group of measurements in comparison to the average value. The precision of field sampling activities was inferred from the consistency of the sampling technique as evidenced in the field audit. The precision associated with field measurement readings was inferred from the duplicate measurements taken at the completion of sampling. All criteria were compliant with existing protocols.
- **Completeness:** Sampling completeness is generally assessed by comparing the total number of samples proposed and obtained. Following the determination by USATHAMA that the analytical data from the original sampling was invalid, the scope of the work assignment was redefined to include 16 soil samples and 2 surface water samples. These sample numbers were used to evaluate completeness of the sampling activities. The number of samples obtained exceeds these criteria.
- **Representativeness:** This criteria expresses the degree of accuracy and precision to which sample data represents the population. The sampling design criteria for the SLOP work assignment consisted of biased sampling locations based on previous site investigations. Samples were collected in compliance with USATHAMA sampling protocols.

5.2.1 Field Audits

A field audit was conducted at SLOP on June 27, 1989. The audit encompassed several areas including: (1) briefing with Project Coordinator; (2) field observations and standard operating procedures; (3) document control; and (4) debriefing with Project Coordinator. No deficiencies were encountered for the standard operating procedures used for the collection of environmental samples. The only deficiency noted during the audit was in the documentation required for the field parameter forms. It was noted that the entries for file name, site identification, and site type were in error. Corrective action was effected by generating an internal memorandum that described the appropriate entries for the respective fields.

A second field audit was conducted at SLOP on September 25, 1990. The areas observed during the audit included: (1) sample documentation and management; (2) field calibration (3) surface water and soil sampling; and (4) additional observations and comments.

A copy of the project work plan was available on site at all times during the sampling activities in the site vehicle. The requisite information was recorded in the logbook to provide evidentiary information that representative samples had been collected.

Surface water samples were collected directly into the requisite sample container. Soil samples were collected using a trenching shovel that had been decontaminated and wrapped in aluminum foil prior to use. An HNu was used to screen the organic composition of the down hole and the environmental samples. The samples were then classified and the requisite information was transcribed into the field logbook, including a sketch of the sampling location.

A stainless steel bowl and trowel were used to homogenize soil samples. Samples requiring volatile organic analysis were not homogenized, but were transferred directly to the sample container. The bowl and trowel were decontaminated between locations with deionized water obtained from Fisher Scientific, which had been approved by USATHAMA for project use. The samples were placed in the

requisite sample containers following homogenization. The down hole generated during sample collection was backfilled with the remaining soil that had been extracted from the hole.

Field calibration was performed on the HNu and the combination pH, temperature, and conductivity meter. All calibrations were performed in accordance with the standard operating procedures for the instrumentation. The temperature sensor of the combination meter was not functioning during the investigation. Conductivity and pH measurements were recorded for samples collected during the surface water investigation.

The sampling team was cognizant of the conventions and protocols associated with surface water and soil sampling. There were no deficiencies associated with this sampling activity.

5.3 ANALYTICAL SERVICES AND DATA QUALITY

Initially, metaTRACE Inc. was responsible for analytical services through a contract laboratory analytical support services (CLASS) contract with USATHAMA. In August 1990, USATHAMA determined that the quality of data acquired from metaTRACE was not adequate to support a site assessment. ESE Laboratories in Gainesville, FL, was then subcontracted directly by ICF KE to provide analytical services for the SLOP task assignment. All analytical methodologies used were USATHAMA-certified and the method quality control and data validation for these analyses were performed by USATHAMA.

5.3.1 Parameters

The constituents requested for analysis included: EPA Target Analyte List (TAL) inorganic constituents; EPA Target Compound List (TCL) volatile and semivolatile constituents; explosives, and Toxicity Characteristic Leaching Procedure constituents (soil samples only). All samples submitted to the laboratory have been identified according to laboratory-designated lot numbers, method numbers, parameters, sampling dates, analytical preparation date (if applicable), and analysis date, as shown in Exhibit 5-1. Analytes, USATHAMA acronyms, certified reporting limits (method quantitation limit), and upper reporting limits for constituents analyzed in support of this project are shown in Exhibit 5-2 (inorganic compounds); Exhibit 5-3 (volatile organic compounds); Exhibit 5-4 and Exhibit 5-5 (semivolatile organic compounds); and Exhibit 5-6 (explosive constituents).

EPA TAL inorganic constituents were analyzed for 23 metals and cyanide in accordance with USATHAMA Class 1 protocols. All water samples were preserved with nitric acid to a pH less than 2.0 following sample collection. The metal constituents were analyzed using one of the following methodologies: inductively coupled argon emission plasma spectroscopy (ICAP), graphite furnace atomic absorption spectroscopy (GFAA), or cold vapor atomic absorption (CVAA). The corresponding USATHAMA method numbers for each designated analysis is given in Exhibit 5-7.

EPA TCL volatile and semivolatile constituents were analyzed in accordance with USATHAMA Class 1A protocols for gas chromatography/mass spectroscopy analysis. USATHAMA methods LM19 was used for the analysis of soil samples and UM 20 was used for the analysis of water samples. The method for the analysis of volatile organic compounds in soil samples involved purging five grams of soil sample and five milliliters of volatile organic free water containing surrogates and internal standards with helium gas. The purging chamber was heated to a predefined temperature and the vapor was transferred to a sorbent tube which effectively trapped the volatile organic compounds. The constituents were then backflushed onto a gas chromatographic column that was temperature programmed to separate the organic constituents. The volatile compounds were then detected using a mass spectrometer. The procedure for the analysis of water samples was analogous to the soil protocol with the exception of the sample used.

LEGEND:

- ^a Analyzed using graphite furnace atomic absorption spectroscopy.
- ^b Background levels in USATHAMA standard soil was too large to obtain realistic CRL values. Results were calculated from water certification.
- ^c Analyzed using spectrophotometric detection.
- ^d Analyzed using cold vapor atomic absorption spectroscopy.

| CVAA | Soil | JB01 (Mercury) |
| | Water | SB01 (Mercury) |

The analytical method for the analysis of semivolatile constituents involved spiking the sample with a known amount of surrogate compounds and extracting a designated amount of sample with methylene chloride. The extract was concentrated to a predefined volume, and internal standards were added to the extract prior to injection onto the chromatographic column. Separation of constituents was performed on the chromatographic column and detection was effected by a mass spectrometer. USATHAMA methods LM18 and UM18 were used for the analysis of soil and water samples, respectively.

Explosives were analyzed in soil and water samples using USATHAMA methods LW12 and UW14, respectively. The soil method involved the extraction of a predefined amount of soil using acetonitrile. The extract was filtered and diluted with a known amount of contaminant free water. The target analytes were then separated on a high pressure liquid chromatography column using isocratic elution, and were detected using ultraviolet absorbance. The water protocol is comparable to the soil technique, but different extraction procedures were used.

5.4 DATA QUALITY OBJECTIVES

Data quality objectives for analytical services were developed during the development of the project work plan and maintained throughout the course of chemical analyses. Quality control samples were analyzed to provide verification that the analytical method performance was comparable or better than levels achieved during initial method certification. Data acquired from the quality control samples were plotted on control charts to assist in the evaluation of the method performance.

In accordance with USATHAMA protocols, ESE was required to submit quality control charts on a frequent basis during sample analysis for USATHAMA review. The quality control charts were used by USATHAMA to monitor the daily variations in the USATHAMA-certified analyses and provide inferences on method performance. The designated USATHAMA project chemist was responsible for evaluating the quality control chart submittals and determining the data acceptability based upon trend analysis. A lot confirmation letter was submitted to the USATHAMA project officer and the ICF KE Quality Assurance Manager. A review of the lot confirmation letters suggested that the control data for lots submitted by ESE were acceptable.

5.5 PHYSICAL DATA QUALITY ASSESSMENT

5.5.1 Survey Protocols

An asbestos survey was conducted to discern the presence of asbestos containing material in the Hanley Area of SLOP. All sampling and survey protocols were performed in accordance with specifications delineated in TM5-612, Asbestos Control, (Draft, January 25, 1989) and the *Guidance for Controlling Asbestos-Containing Materials in Buildings* (EPA 560/5-85-024).

The survey consisted of an initial review of building drawings and facility documents to identify highly suspected areas for the presence of asbestos containing material (ACM). Materials were inspected throughout each building and the tunnel system. Information pertaining to the location, amount, condition, and potential disturbance of suspect ACM was recorded in the field logbook. Highly suspect samples were submitted to the laboratory for the analysis of asbestos content. In addition, a duplicate or "split" sample was collected to evaluate the accuracy of field sampling techniques.

The suspect ACM samples were collected in accordance with industrially acceptable standard operating procedures by an Asbestos Hazard Emergency Response Act (AHERA) certified inspector. Samples were collected to be representative of the sampling area.

5.5.2 Laboratory QA/QC

The laboratory responsible for analyzing insulation material for asbestos content was Certified Engineering & Testing Company (CETCO), Weymouth, Massachusetts. CETCO participates in three national accreditation and certification programs: NIOSH Proficiency in Analytical Testing (PAT) program required for an AIHA proficient lab; AIHA Asbestos Analyst Registry (AAR); and the National Voluntary Laboratory Accreditation Program (NVLAP) as mandated by the AHERA regulations, 40 CFR 763.

CETCO has a documented quality assurance program in place to ensure the accuracy and precision of systems involved in asbestos analysis. The quality assurance program provides standard operating procedures and structured quality control protocols to identify and minimize out-of-control occurrences.

CETCO provided bulk asbestos analysis for samples collected by ICF KE using EPA Method 600/M4-82-020 "Interim Method of the Determination of Asbestos in Bulk Insulation Samples". To ensure the accuracy of bulk sample analysis for asbestos containing material, CETCO processes a minimum of 10% quality control samples.

5.6 BLANK CONTAMINATION ASSESSMENT

Several rinse and trip blanks were collected to discern the potential for field contamination of environmental samples during collection activities. The analytical results from these samples are summarized in Exhibit 5-8.

5.6.1 Organic Contamination

Methylene chloride was detected at a concentration of 6.3 µg/L in soil rinse blank SORB-2. The water used to generate the rinse blank was Fisher Scientific deionized, ultra-filtered water. In accordance with USATHAMA field sampling protocols, no solvents were taken into the field during sampling activities. Methylene chloride could not have been acquired in the field as evidenced by the following facts: (1) none of the associated samples were contaminated with the constituent; (2) the trip blanks associated with the samples did not contain methylene chloride contamination; and (3) the initial soil rinse blank did not contain methylene chloride above the certified reporting limit. Although the laboratory method blank did not contain methylene chloride, the constituent is a common laboratory contaminant. Methylene chloride at part per billion (ppb) concentrations is often detected in the laboratory environment. The concentration of methylene chloride in the rinse blank is an inconsequential factor since none of the environmental samples contained the compound.

5.6.2 Metal Contamination

Several metals were detected above the certified reporting limit in the two soil rinse blank samples and the method blank associated with Lot TGQ. The following subsections discuss the results obtained and the impact on the associated samples.

Copper: Copper was detected in soil rinse blank SORB-1 at a concentration of 66.8 µg/L and in rinse blank SORB-2 at a concentration of 30.4 µg/L. A review of the associated soil samples did not indicate the presence of copper.

EXHIBIT 5-8

BLANK CONTAMINATION RESULTS

| BLANK | SAMPLING DATE | RESULTS | |
|------------------------|----------------------|--|--|
| SORB-1 ^a | 09/24/90 | GFAA metals Copper Iron Zinc Lead Mercury Explosives VOAs | < CRL ^b 65.8 µg/L 67.2 µg/L 44.1 µg/L 3.7 µg/L < CRL < CRL < CRL |
| SORB-2 | 09/25/90 | GFAA metals Copper Iron Zinc Lead Mercury Explosives Methylene Chloride | < CRL 29.9 µg/L 85.5 µg/L 30.0 µg/L 2.3 µg/L < CRL < CRL 6.7 µg/L |

| Method Blank - Lot TGQ | Not Applicable | Iron | 61.3 µg/L |

LEGEND:

- a - SORB-soil rinse blank
- b - CRL-certified reporting limit
- c - SOTB soil trip blank

Iron: The concentration of iron in soil rinse blanks SORB-1 and SORB-2 were 71.6 µg/L and 91.1 µg/L, respectively. Iron was also detected at a concentration of 61.3 µg/L in Lot TGQ, which included samples for water analysis of metals. The iron contamination in the rinse blanks was acquired from the laboratory environment as evidenced by the level detected in the lot method blank. Iron was not detected in the associated soil samples.

Lead: Lead was detected in rinse blank SORB-1 at a concentration of 4.0 µg/L and in soil rinse blank SORB-2 at a concentration of 2.5 µg/L. The soil rinse blanks were analyzed for lead concentration using graphite furnace atomic absorption spectroscopy (GFAA), while the associated soil samples were analyzed using inductively coupled argon emission spectroscopy (ICAP). The GFAA method for the detection of lead is approximately ten times more sensitive than the ICAP method. The levels of lead detection in these samples could have been acquired from a variety of sources and operations including: (1) sample digestion; (2) laboratory environment; or (3) cross contamination from the graphite furnace tube. The lead could have been acquired during sample digestion if the reagents used during the digestion process contained lead contamination. The residence time in the laboratory environment prior to sample analysis could have contributed to lead contamination. Residual lead may have come into contact with the samples through leaching from fume hoods, laboratory equipment, or other material that could be impacted by the corrosive action of acids used in metals analysis. The possibility also exists that the samples could have been cross-contaminated from the furnace tube. The rinse blanks were noted as being run numbers 32 and 34 in the Lot TUE associated with the samples. This lot contained samples from two other installations. Concentrations in the other samples, and whether an equipment rinse blank was processed after high level samples to preclude the occurrence of cross-contamination, are unknown.

Zinc: Zinc was detected in soil rinse blanks SORB-1 and SORB-2 at concentrations of 46.4 and 31.6 µg/L, respectively. Zinc was detected in the associated samples and the impact on the analytical data can not be estimated from the existing information.

5.7 BACKGROUND SAMPLES

A total of six background soil samples were collected from SLOP in areas not likely to be contaminated. These samples were analyzed to develop site-specific background values for various elements in soil.

In addition, outside sources were consulted to determine regional background levels of selected constituents. Concentrations of various metals were obtained from a USGS paper on the geography of soil geochemistry in the State of Missouri. The source indicated metal concentrations in agricultural soils within the State. Staff at the Missouri Department of Natural Resources affirmed that these data are indicative of native soils. Reported results included samples from within the glaciated region where SLOP is located, and less than fifteen miles from the site. The USGS sampling locations are represented by frequency classes which fall within a concentration range based on the total samples taken in the state. When the two sampling locations under investigation fall within the same frequency class, the mean concentration of the range is taken as the regional background level. When represented by different frequency classes, the mean is calculated along with the 95% confidence interval in order to obtain a representative concentration range for the samples under investigation. In most cases, this interval was less than 1 ppm and the background value is represented by its mean only. Zinc and lead are the only metals represented by a range due to a 95% confidence interval greater than 1 ppm. Regional background concentrations for inorganic analytes and results of inorganic analyses for background soil samples are shown in Exhibit 5-9. Most of the metals concentrations found in background soil samples collected at SLOP are at or below regional background values. However, concentrations of lead, nickel,

NRQ = analysis not requested for this sample.

and zinc in some of these samples exceed regional background levels (see Exhibit 5-9). For example, soil sample SS54A has a lead concentration twice the regional background range.

Some semivolatile organic compounds were observed at trace levels (<1 ppm) in the background soil samples (see Exhibit 5-10). The compounds observed belong to a group of compounds known as polycyclic aromatic hydrocarbons (PAHs). Although all the compounds listed can occur naturally in soil (Dragun 1988), their presence is probably due to the proximity of the sampling locations to an asphalt parking lot. Background samples were collected within 10–40 feet of an asphalt parking lot and traces of asphalt were reported in the physical description of some of these samples.

6.0 INVESTIGATIVE RESULTS AND CONTAMINATION ASSESSMENT

A site assessment study was performed at the Hanley Area to: (1) determine the nature and extent of site contamination; (2) evaluate contamination migratory characteristics; (3) investigate potential contamination impacts upon receptors; and (4) define alternative remedial strategies. An asbestos survey and surface soil and tunnel water investigations were conducted to establish baseline information on potential pollutants. This section of the report discusses the investigations performed in support of this project and is limited to the information acquired from the asbestos location survey and the surface soil and tunnel system water sampling conducted in September, 1990. Specific remediation alternatives are discussed and evaluated in Section 7.0. All chemical analytical data obtained during the investigation are shown in Appendix A.

6.1 SOURCES AND DISTRIBUTION OF ASBESTOS CONTAINING MATERIAL (ACM)

Airborne asbestos contamination in buildings presents significant health risks to personnel exposed to these conditions. The presence of ACM in a building does not necessarily constitute a hazardous condition when the ACM is in a good condition and is not disturbed. Any ACM present becomes a potential hazard when activities are undertaken that disturb or damage the ACM.

An asbestos location survey was conducted in the Hanley study area to determine the location and distribution of friable and nonfriable ACM. The survey covered all accessible areas and included buildings, basements, tunnels, and exterior steam pipes. Pipes were color coded with spray paint during the inspection, where accessible, to visually delineate the areas of ACM. Red dots and arrows were used to denote and bracket the areas of ACM. The color blue was used in a similar manner to denote other materials. Suspect ACM samples were submitted to a certified asbestos analysis laboratory to determine the percent asbestos by weight. *EPA criteria were used for defining asbestos, i.e., whether the asbestos weight content is greater than one percent.* Results obtained from the asbestos sampling, shown in Exhibit 6-1, reveal that many construction materials and pipe insulation in the Hanley Area are classified as ACM.

The information acquired from the survey was sufficient to make estimates of the condition of ACM and the development of remediation strategies for abatement. Approximately six (6) miles of ACM on pipe lagging was identified in the Hanley study area. The following sections present the findings of the asbestos survey for each investigative area.

6.1.1 Source Areas

Tunnels

Tunnels surveyed included all cross hatched areas depicted in Exhibit 3-1 (Pocket A) and the six elevated crawl spaces leading to the 219 bunkers (west bunkers). There are approximately two linear miles of ACM lagging on pipes within the tunnels.

Basements

Basement spaces beneath six buildings and two groups of bunkers shown on Exhibit 3-1 (Pocket A) were surveyed during the asbestos survey. Included in this survey were three basements associated with Buildings 218A, 218B, and 218C; one basement and two crawl spaces associated with Buildings 219A, 219D, and 219G; and four basement rooms under the 228 series of bunkers, which are divided into two groups. There are no basements under the 227 series of bunkers.

| AB-011 | Red "spark proof" floor/Warehouse 219 G | 1-5% Asbestos (Chrysotile) |

¹ Limited asbestos survey conducted by ICF KE from June 28-30, 1989.

The three Building 218 basement spaces each contained an estimated 1,080 linear feet of ACM, which is in good condition and does not present an imminent hazard. An additional 120 square feet of ACM in these basements was found to be associated with a small and a large heat exchanger located in each of these three basements. A sample of the ACM showed that the large heat exchanger jacket contains approximately 75 square feet of chrysotile and amosite asbestos. Visual inspection indicated that the small heat exchanger contained the same material as the large heat exchanger. The small heat exchanger contains approximately 45 square feet of ACM. The three basements located beneath buildings 219A, 219D, and 219G contain a total of 1,320 linear feet of ACM that is not friable and in good condition.

The basement below bunkers 228A, 228B, and 228C contains 570 linear feet of ACM, while the basement below bunkers 228D, 228E, and 228F contains 620 linear feet of ACM. The ACM in these basement spaces remains in good condition. The basement beneath 228M/Y-North contains 620 linear feet of ACM. The basement beneath 228G/Y-South contains 800 linear feet of ACM that is non-friable and in good condition. The 228M/Y-North basement contains approximately 100 linear feet of broken lagging were found on the floor or leaning from pipe to floor. This condition could pose an environmental health hazard if the ACM was friable and someone was present in the area.

Buildings and Floors

Approximately three lineal miles of ACM were identified in above-ground pipe lagging associated with the chilled water return, chilled water supply, steam, and hot water pipes located in buildings 218A, 218B, and 218C. In addition, 800 lineal feet of ACM was found on pipe lagging in 26 bunkers. During the survey, one sample of red "spark proof" flooring showed the presence of chrysotile asbestos. Based upon this finding, the installation submitted 14 additional samples to a different accredited laboratory, which corroborated the initial results and estimated a high probability that all red "spark proof" floors contain chrysotile. A number of the flooring locations have buckled from exposure to moisture and weathering. In some cases, the floor can be pulverized with normal finger pressure and can therefore be classified as friable.

Only 11 of the 16 bays associated with the 227 bunkers were accessible at the time of the ACM survey. Bunkers located in the 227 block in the south portion of the site contain transite exterior shingles. Analysis of the shingle material indicates a chrysotile asbestos content of 75-80% by weight. Each of the bunkers contain approximately 350 square feet of exterior shingles for a combined total of 3,850 square feet of ACM. Although approximately ten (10) percent of the shingled surface area appeared to be damaged, the asbestos is tightly bound in the matrix and does not represent friable material.

6.2 TUNNEL SYSTEM WATER

Two tunnel system water samples were collected from utility tunnels located approximately 12 feet beneath the Hanley area, and identified as samples SW09 and SW10. Samples were analyzed for EPA Target Analyte List (TAL) inorganic constituents and EPA Target Compound List (TCL) volatile and semi-volatile organic compounds as well as explosives.

Sample SW09 was collected in the tunnel access area across Goodfellow Boulevard, at the base of the tunnel ladder. Samplers noted that the water was stagnant. This area is not blocked off from access in the direction of privately owned property.

Sample SW10 was collected near a vent of the tunnel system in the northwest quadrant of the study area. The vent area has an additional twelve foot drop off. Standing water in the tunnel was approximately six inches deep. During the sampling activity, water infiltration (discharge from a leaking

pipe) was noted. The origin of the leak (type of pipe) was not confirmed, but appeared to be a broken municipal water line. The water flowed due north through Building 220 and potentially into the drainage system along Stratford Avenue.

As of July 16, 1991, all utility lines within the tunnel system were inactivated. Standing pools of water are no longer observed in the tunnel system. A potential pathway for water entering the tunnel system still exists (i.e., surface water runoff), but the amount of standing water received will be negligible.

6.2.1 Inorganic Contamination

Tunnel system water samples were analyzed for 23 metals and cyanide. Metals detected above the method certified reporting limits include aluminum, barium, calcium, chromium, copper, iron, lead, potassium, magnesium, manganese, sodium, and zinc. The results of these analyses are presented in Exhibit 6-2. The presence of these constituents in surface water samples is consistent with the types of past operations and compounds used in the study area.

Federal regulations for surface water quality are not applicable to the water located in these tunnels. The probability of this water being accidentally ingested is extremely low, therefore the Federal drinking water regulations would not be applicable. The most appropriate regulation for the study area is the Metropolitan St. Louis Sewer District (MSLSD) Ordinance No. 4786, which is applicable to the introduction of pollutants into the municipal wastewater system. Exhibit 6-3 contains a list of the effluent discharge limits for the MSLSD compared to analytical data acquired for the surface water samples. The MSLSD ordinance specifies that the listed pollutants shall not exceed a 24 hour concentration in the wastewater as measured at a point prior to discharge to the public sewer, and at no time shall the pollutant exceed three (3) times the average 24 hour concentration specified regardless of wastewater flow. Lead is the only metal detected with the potential for posing a threat, with concentrations close to the effluent limit in sample SW10 and exceeding the limit by a factor of two in sample SW09. However, these samples were not collected directly at the discharge point and the impact cannot be quantified.

6.2.2 Organic and Explosive Contamination

Volatile and semivolatile organic compounds were not detected above their respective certified reporting limits in either of the tunnel system water samples. One explosive, Pentaerythritol Tetranitrate (PETN), was detected at a concentration of 20 µg/L in sample SW09, which is also the method certified reporting limit for this constituent. PETN is the most sensitive of the secondary high explosives in general use and was used as an initiating agent during prior operations in the Hanley Area. Currently, there are no health advisories for this constituent.

6.3 SURFACE SOIL SAMPLES

Surface soil samples were collected, classified, and analyzed to determine the type, levels, and horizontal extent of hazardous contamination. A total of twenty-nine (29) surface soil samples were collected and analyzed for chemical constituents in support of this investigation, (refer to Exhibit 3-2 (Pocket B) for sampling locations). Samples were collected at a depth of 0-1 foot and 1-2 feet at each location with the exception of locations SS41 and SS42 where auger refusal was encountered at a depth of less than two feet due to the presence of a concrete slab upon which Bunker 228E rests. All samples were analyzed for metals and explosives, the major analytes of concern at the site. Samples collected at the 0-1 foot depth interval were generally analyzed for sixteen (16) ICAP metals, explosives, and mercury, with the exception of SS41 which was analyzed for the full TAL/TCL and explosives. Samples

the full TAL/TCL and explosives. Samples collected at the 1-2 feet depth interval were analyzed for TAL/TCL and explosives, except for samples SS40, SS43, SS45, SS49, and SS50 which were analyzed for ICAP metals and explosives.

6.3.1 Background Samples

Samples from three background locations (SS40, SS53 and SS54) were obtained in support of this investigation. The samples were collected in a grassy location outside of the study area but within the original SLOP property boundaries. Sample SS40 was located approximately 500 feet southwest of the intersection of the security fences, which served as a reference point. The reference point itself is in the far west corner of the Hanley area (see Exhibit 3-2). SS53 was located 750 feet southwest of the reference point, and SS54 was located approximately 850 feet from the reference point. The majority of the analytical constituents were not detected above the State of Missouri regional background concentrations, (Tidball, R., 1984, Geography of Soil Geochemistry of Missouri Agricultural Soils; Geochemical classification by Factor Analysis of Missouri Agricultural Soils, USGS Professional Paper 954-HI, Washington, D.C.), with the exception of lead in SS54 and zinc in all of the samples.

Lead was detected at a concentration of 52.4 $\mu\text{g/g}$ in the 0-1 foot interval and at a concentration of 23.3 $\mu\text{g/g}$ in the 1-2 feet interval at location SS54. Although lead concentrations were significantly above regional levels (23-25 $\mu\text{g/g}$), EPA has not established proposed action level for soil samples.

Zinc was detected at concentrations of 142, 110, and 112 $\mu\text{g/g}$ in the 0-1 foot interval of samples SS40, SS53, and SS54, respectively. The corresponding concentrations in the 1-2 feet interval were 92.6, 109, and 86 $\mu\text{g/g}$. The regional background concentration for zinc ranged between 89-107 $\mu\text{g/g}$.

6.4 NON-BACKGROUND SAMPLES

6.4.1 Inorganic Contamination

With the exception of a few elements, all metals were found to be at or below site-specific background concentrations and the State of Missouri regional background levels. The analytical results are shown in Exhibit 6-4. The only constituent detected in several of the sampling locations above regional background concentrations was lead. Exhibit 6-5 lists the lead concentrations found which were above the regional levels, and describes prior activities associated with each sampling location. Primer materials containing lead azide are a likely source of the lead found in these samples. Lead was detected at higher concentration in the 0-1 foot interval and at decreased concentrations for the lower depths (exceptions are samples SS46 and SS49, which had higher lead concentrations for the 1-2 feet interval. However, the area where these two samples were taken are areas which may have received some clean soil which was brought in to fill low spots. Therefore these "B" samples at depth would then become equivalent to other surface "A" samples.). As discussed in Section 4 of this report, the State of Missouri has not developed clean up levels for contaminants in soil.

6.4.2 Organic Contamination

No explosives constituents were detected in any of the soil samples. The samples were generally free of organic contamination with the exception of polychlorinated biphenyls (PCBs) in sample SS55 (0-1') and polynuclear aromatic hydrocarbons (PAHs) in trace concentrations in samples SS41 (0-1'); SS44 (1-2'); SS48 (1-2'); SS51 (1-2'); and SS52 (1-2'). The analytical results are shown in Exhibit 6-6. SS55 was collected below a transformer at bunker 228C. The analysis confirmed the presence of PCB-1260 at a concentration of 17,900 $\mu\text{g/g}$. The PAHs were detected at low levels, probably attributable to constituents present in the fill material.

6.4.3 Toxicity Characteristic Leaching Procedure

The toxicity characteristic leaching procedure (TCLP) was used to analyze four soil samples, to determine if these soils could be considered hazardous because of toxicity. The sampling locations were SS41 (0-1'), SS44 (1-2'), SS47 (1-2'), and SS51 (1-2'), (refer to Exhibit 3-2-Pocket B). The analytical results are shown in Exhibit 6-7. Sample SS41 was collected on the west side of the 228 series bunkers. The 228 area had previously been associated with explosives storage. Sample SS44 was collected in the vicinity of the 227 series bunkers, 16 yards south of a gate entrance within the security fence. These bunkers were also used for the storage of explosives. Sample SS47 was collected at the west end of Building 219G, which had previously been used for the loading of explosives during cleanup operations. Sample SS51 was obtained from a grassy area east of Building 218A. This building was used for non-explosive storage. No volatile or semivolatile TCLP organic compounds were detected above their respective certified reporting limits in any of these 4 samples. Barium, cadmium, and lead were the only inorganic analytes detected above the method certified reporting limit, at concentrations far below regulatory limits (see Exhibit 6-7). If the four sampling locations are assumed to be representative of surface soil at the site, then it is likely that none of the surface soil on site would be classified as hazardous because of toxicity. The TCLP results also indicate a low potential for leaching of metals from the soil matrix. Concentrations of leachable metals in the soil matrix are related to leachate concentrations from the TCLP results by considering the volume of extraction medium (2L) and the amount of soil extracted (100 g). For example, TCLP results for sample SS41A (LT 18.6 $\mu\text{g/L}$) correspond to a leachable lead concentration of less than 1.0 $\mu\text{g/g}$ in the soil, compared to a total lead concentration of 155 $\mu\text{g/g}$ provided by ICAP analysis. Similar results indicate that none of the metals detected in the soil samples would be leached readily from the matrix.

6.5 CONTAMINATION AND EXPOSURE ASSESSMENT

6.5.1 Asbestos-containing Materials

Significant amounts of construction materials and insulation containing ACM were found throughout the Hanley Area. Most of the ACM are found inside buildings, bunkers, or tunnels and some of the sources are intact and protected. There is also a high probability that asbestos has contaminated dust and soil within, beneath, and surrounding those structures containing source materials in a state of disrepair. All of the ACM are in restricted areas where access is occasional and limited to authorized personnel. Thus, direct exposures to airborne ACM under current site conditions are not significant except from potential low levels that might be entrained in wind-blown dust.² However, the type and extent of ACM are such that any renovation, demolition, or clean-up activity will require specific precautions to minimize exposures to airborne asbestos fibers. Any activity involving disturbance of construction materials (and possibly also dust and soils) in the Hanley Area has a high potential for resulting in both on-site and off-site exposures unless stringent precautions are exercised.

²At the time of the field investigation, access to areas within the security fences by unauthorized personnel is not completely restricted; evidence of recent trespassing and vagrancy (including food wrappers, ashes from fires, bedrolls, and blankets) were noted in the building basements, tunnels, and bunkers. Several access means including a hole in the security fence and two tunnel exits connecting to outside areas were found at the site. Thus, accidental exposure to contaminants at the site (including asbestos and materials found in water and on building surfaces) were possible. Since July, 1990, access control to the area has been significantly increased.

LT = less than certified reporting limit.

6.5.2 Tunnel System Water

Tunnel system water containing metals and one explosive detected at the method certified reporting limit was observed in the field work conducted in September, 1990. At that time, tunnel system water had migrated or had a high potential for migrating beyond the controlled boundaries of the Hanley area. The potential for exposures to this contamination appeared to be limited, but uncertainties remained about the fate of the discharges beyond the site boundaries.

During the September 1990 field work, flowing water present in the south-north tunnel discharged directly to the surface and/or subsurface near the northern property boundary of the Hanley Area adjacent to Building 220, and an observed swampy area along the boundary fence north of the building was thought to be a result of this discharge. Thus, it was determined that there was a high potential that lead contamination found in water within the tunnel was migrating off site. During a site tour by USATHAMA in July, 1991 no swampy area was observed along the boundary fence north of Building 220. By this point in time, all utility lines running beneath the Hanley area had been inactivated, and thus the source of flowing water observed in September, 1990, had been removed.

Contamination was also found off site in standing water within the west-east tunnel that extends across Goodfellow Boulevard. The tunnel vent at the sampling point is on property previously within the original SLOP boundaries and currently owned by the Goodenough Box Company.³ Because of the essentially unrestricted access, there is a potential for human contact with the stagnant water in the tunnel. (Access is possible, in fact, to other portions of the tunnel system.) The fate of water downgradient from this point in the tunnel is not certain, although a brick wall in the tunnel adjacent to the vent might hinder further migration. It is expected that water from the tunnel ultimately discharges to the surface several hundred yards east of the Hanley Area. No flow in this tunnel was observed during three visits to the site, although there was evidence of periodic sediment deposit and removal that could only occur if water flowed along the tunnel floor.

6.5.3 Building and Surface Soil Contamination

Previous studies have noted several areas with a high potential for explosives and metals contamination, and the current study focused on determining whether contamination within the structures has resulted or could result in unacceptable exposures and risks. Sampling of surface soils in the Hanley Area, although of limited scope, indicates a low potential for exposures via contact with runoff from the surface. No explosive contamination was found in these soils, and analysis of soil samples for inorganic constituents showed concentrations of most metals to be at or below site-specific background levels and regional background levels. Lead appears to be the metal of greatest concern in the Hanley Area. The concentrations of lead detected in the surface soil matrix exceeded site-specific background values at 7 sample locations, including five in the vicinity of Buildings 218B, 218C and 219G area and two locations in the 228 series magazine area. Lead concentrations at these seven sample locations also exceeded regional background values. The relatively widespread occurrence of lead in the soils and (and as indicated in previous reports) within the buildings correlates well with diverse former operations involving primer materials at the site. The levels and extent of lead in soil may constitute potential exposures via windblown particulate matter and surface runoff migration. Potential exposures from direct contact with the soils or from contamination of groundwater are not considered to be significant.

³There is a possibility that contamination observed at the base of the tunnel vent originated from the adjacent property rather than migrating down the tunnel from the Hanley Area. The vent allows infiltration of surface runoff from the surroundings, which were originally part of SLOP and may contain contaminated media.

Barium concentrations exceeded site-specific background values in soil samples at two locations in the Building 218C area; these concentrations did not exceed regional background values. Chromium concentrations exceeded site-specific background values at one location, north of the Building 218C area; this concentration did not exceed regional background values. Zinc concentrations exceeded site-specific background values at two sample locations, both in the Building 218C area; these concentrations also exceeded regional background values. The occurrence of all of these metals can be related to operations conducted within the Hanley Area. Because of the relatively low maximum values and the low average concentrations found across the site, the levels of these metals in the soil matrix do not appear to pose unacceptable direct exposure threats.

Trace levels (< 1ppm) of polycyclic aromatic hydrocarbons (PAHs), a group of semivolatile organic compounds associated with combustion byproducts and petroleum still bottoms including tar and asphalt, were found in 14 of the soil samples collected. These occurrences may be attributed to the degree of asphalt paving and roofing in the area and perhaps to fill materials used in constructing SLOP, and probably are not indicative of specific PAH sources at the site. The levels observed are less than or equal to commonly-encountered concentrations of these materials in an urban setting, and do not pose a significant threat to human health or the environment.

The toxicity characteristic leaching procedure performed on 4 soil samples indicated that soils would not be considered to be hazardous on the basis of toxicity. Thus, any potential soil-related actions at the site likely would not be hindered by requirements for disposal of hazardous wastes. The TCLP results also show that the leachability of metals from the soil matrix is low, resulting in a low potential for migration of contaminants into groundwater. It is also likely that surface-soil metals contamination has not migrated into the soil column to a significant extent.

Lead and explosives deposits within the buildings and subterranean structures in the Hanley Area may pose health hazards during demolition or renovation activities. Any release of contaminants onto the surface or into the tunnel system during cleanup activities will exacerbate the current exposure potential from these media/migration routes.

6.5.4 PCB Contaminated Transformer and Soil

The high concentration of PCBs found in soil beneath the leaking transformer at bunker 228C posed an unacceptable situation both from the standpoint of regulatory requirements and health risk concerns. In spring of 1991, the transformer was demounted and protectively wrapped. The transformer as well as the underlying contaminated soils will be properly disposed of by the U.S. Army Engineer Center and Fort Leonard Wood. Inspection of the ground under the location of the transformer reveals that the area is asphalt that has become slightly covered with earth. Based on field observations, there is no possibility of groundwater contamination. The transformer fluid has the viscosity of molasses and has not been observed to mix with precipitation or runoff. In fact, the sticky nature of the fluid has caused dust, soil, and vegetation to adhere to it.

6.6 CONCLUSIONS

- ACM are present in most areas within the Hanley Area, and some of these materials should be removed and/or repaired. The ACM problem associated with potential demolition or renovation activities will be particularly severe.
- Surface soils are contaminated with lead at levels of potential concern. Major potential migration pathways relate to surface runoff and windblown dust.

- Water in the tunnels is contaminated with lead and possibly an explosive at levels of potential concern. Although the main source of standing water in the tunnels has been removed, water from infiltration and surface runoff may still carry contamination into the tunnel system.
- Buildings, bunkers, and possibly the tunnel system contains metals and explosive contamination which may have contributed to soil and water contamination. Disrepair of the structures has exacerbated this situation.
- A leaking transformer containing a high concentration of PCBs contaminated a limited amount of soil. The transformer has been demounted and protectively wrapped, and both the transformer and contaminated soils are in the process of being properly disposed of.

7.0 RECOMMENDATIONS

7.1 RECOMMENDATIONS FOR INTERIM AND LONG-TERM CORRECTIVE MEASURES

7.1.1 Asbestos Containing Materials

1. Operations and Maintenance Program

It is recommended that the Army establish an Operations and Maintenance (O&M) program that addresses all areas of the St. Louis Ordnance Plant containing asbestos. This program should address abatement planning and monitoring requirements, and provide information to members of the public who may come in contact with the asbestos at the facility, including any contracted laborers, workmen, military and civilian Army personnel.

OSHA and AHERA regulations require that workmen require notice when performing work on the property if their activities could result in exposure to airborne asbestos fibers. This exposure can occur from work performed on ACM or from work in close proximity to ACM. The bulk sampling for asbestos conducted during the survey confirmed the presence of asbestos in many materials and areas at the site, as described in Section 6.

During the initial phase of the Operations and Maintenance program, trained employees should repair damaged ACM and remove ACM that are not intact or protected from airborne dispersal. Establishment of a contract for this work may require a detailed inventory of all ACM at the facility. All repair work will require respiratory protection (air purifying respirator with HEPA cartridges) for workers and activities should occur in such a manner that fiber generation is minimized. The Operations and Maintenance program should specify periodic air sampling, air sampling following potential episodic releases (e.g., extensive damage to ACM pipe lagging), repair of friable ACM, training of Operations and Maintenance personnel on the health hazards of exposure to airborne asbestos fibers, and training on the use of appropriate respiratory protection. The Operations and Maintenance program should remain in effect until such time that all ACM at the facility has been appropriately remediated.

2. Removal Options

The costs of removing asbestos has increased dramatically over the past few years, which is attributable both to more stringent regulations regarding the removal of asbestos and to increased costs for asbestos liability insurance for abatement companies and asbestos consultants. Asbestos materials costing approximately \$0.50 per linear foot to install in the early 1950s now require an average of \$30 per linear foot to remove in many regions of the country including St. Louis, Missouri. Because the cost of asbestos abatement is expected to continue increasing, it is recommended that the Army explore options for appropriate management of the asbestos situation in the Hanley Area at SLOP, without the need for complete removal of all ACM.

The first priority in asbestos removal should address aboveground, potentially friable ACM. Removal of all aboveground asbestos with potential friability under normal use conditions is recommended. This includes all deteriorated pipe lagging within buildings and the steam lines that serviced the south bunkers. Asbestos-containing exterior shingles and the red "spark proof" flooring that is in good condition would not require abatement unless the materials are demolished, because these materials lack friability unless disturbed. In locations where the floor has buckled because of moisture infiltration, the material has become friable and easily pulverized by normal finger and hand pressure. Because at least

occasional occupancy of Buildings 219A, 219D, and 219G is planned, removal of the floor materials from these areas is recommended.

The most troublesome, friable asbestos in above-ground areas was found in portions of Buildings 218A, 218B, and 218C, and removal of these materials should precede any demolition (if planned) or further deterioration of the structures. Asbestos elsewhere in the Hanley Area, at a minimum, should be monitored for changes in the potential hazards posed.

Abatement of asbestos lagging in the tunnels and basement spaces should be abated by severely controlling access. Entombment of major sections, if not all, of the tunnel system is considered to be the best remedy. This option would guarantee that site access is denied, reducing the potential for accidental exposures both to asbestos and to chemical contamination. Securing all openings with an impenetrable barrier (e.g., concrete wall) and filling the tunnels at vents and other locations will eliminate trespassing and reduce the risk of additional damage to the asbestos pipe lagging. Additional engineering evaluation should precede implementation of an entombment option.

Most of the pipe lagging in basements and tunnels remains in good condition and does not need to be addressed immediately. However, an estimated 620 linear feet of ACM lagging in the basement under bunkers 228M and 228Y (North) require abatement. Much of this ACM is water-damaged and approximately 100 linear feet have fallen from the pipes or is hanging loosely from the pipes.

Three potential options for asbestos abatement actions in the Hanley Area have been considered. For each option, the proposed actions and costs associated with those actions are described in the sections that follow. The first option represents the minimum action level, the second option represents an intermediate action level, and the third option represents complete removal of all known ACM. The cost estimates shown reflect only asbestos-related activities, and the cost of coincidental demolition or other corrective measures are not included. Exhibit 7-1 summarizes the results of the asbestos survey. It should be noted that only 11 of the 16 bays associated with the 227 bunkers were accessible for inspection. For the purposes of this report, it was assumed that the 5 bays that were not inspected were identical to the inspected bays, and estimated amounts and costs for asbestos abatement of these 5 bays are reflected in the various options and associated cost estimates.

3. Option I

For this option, damaged ACM would be repaired or removed when repair is not possible, and non-intact ACM would be removed and disposed of in a Missouri-approved asbestos landfill. An ongoing Operations and Maintenance program would be established to address the existing ACM at the facility. Approximately 15 percent of the total ACM would be repair or removal. As shown in Exhibit 7-1, an estimated 32,350 linear feet of ACM and 55,960 square feet of ACM exists in the Hanley Area. Fifteen percent of this total represents approximately 4,850 linear feet and 8,400 square feet. Using an estimate of \$10 per linear foot or square foot for repair or removal when repair is not possible, this option would result in an abatement cost of \$132,465. The approximately 600 linear feet of non-intact ACM pipe lagging would cost approximately \$12,000 to remove and dispose properly in an approved asbestos landfill. Implementation of an O&M program as outlined above would cost an estimated \$15,000 per year. Thus, the total estimated cost for Option I is \$144,465 plus \$15,000 per year of O&M costs. Cost data are presented in Exhibit 7-2.

4. Option II

For this option, all aboveground ACM with the exception of the exterior transite shingles would be removed, ACM in the tunnels or basements would be repaired, most tunnel and basement entries would be permanently blocked, and those entry points necessary to access for O&M would be secured.

EXHIBIT 7-1

ASBESTOS SURVEY RESULTS

| Location | Type of ACM | Estimated Amount |
|-------------------------------------|---------------------------------|----------------------------------|
| Tunnels | Pipe Lagging | 10,500 linear feet (lf) |
| Basements | Pipe Lagging Thermal Jackets | 7,170 lf 360 square feet (sf) |
| Building Interiors | Pipe Lagging Red Flooring | 13,800 lf 50,000 sf |
| 227 Bunkers (11 of 16 Inspected) | Exterior Transite Siding | 5,600 sf |
| Exterior Steam | Pipe Lagging | 880 lf |

EXHIBIT 7-2

ESTIMATED REMOVAL COSTS FOR ASBESTOS CONTAINING MATERIALS (ACM)^a

OPTION I

| Location | Type of ACM | Estimated Amount | Unit Cost for Repair/Removal | Cost (\$) |
|--|---------------------------------|----------------------|------------------------------|------------------|
| Tunnels | Pipe Lagging | 1,575 lf | \$10/lf | 15,750 |
| Basements | Pipe Lagging Thermal Jackets | 1,075.5 lf 54 sf | \$10/lf \$10/lf | 10,755 540 |
| Building Interiors | Pipe Lagging Red Flooring | 2,070 lf 7,500 sf | \$10/lf \$10/lf | 20,700 75,000 |
| 227 Bunkers (11 Total) | Exterior Transite Siding | 840 sf | \$10/sf | 8,400 |
| Exterior Steam | Pipe Lagging | 132 lf | \$10/lf | 1,320 |
| Removal of 600 lf of non-intact ACM pipe lagging | | | | \$12,000 |
| Total lf: 4,852.5 = 4,850.0 | | | | |
| Total sf: 8,131.5 = 8,140 | | | | |
| Total Capital Cost | | | | 144,465 |
| O&M Cost (per yr) | | | | 15,000 |

^a The estimated removal costs include all costs associated with removal of ACM. These services include development of specifications, canvassing of three competent contractors, asbestos removal, transportation, contractor monitoring, air monitoring, and disposal. These costs assume union labor; mobilization/demobilization from St. Louis, Missouri; 1989 pay scales; and \$25 per cubic foot for disposal of ACM in an approved Missouri asbestos landfill.

^b At present only the red flooring in the three warehouse buildings (219A, D, and G) has been sampled. ICF KE has assumed that red flooring throughout the facility is ACM. The cost estimate provided for the flooring also assumes that the flooring can be removed as non-friable ACM without the need for polyethylene enclosures, HEPA air traps, etc.

EXHIBIT 7-3

ESTIMATED REMOVAL COSTS FOR ASBESTOS CONTAINING MATERIALS (ACM)^a

OPTION II

| Location | Type of ACM | Amount to be Repaired or Removed | Cost for Repair/ Removal (\$) |
|---|---|----------------------------------|-------------------------------|
| Tunnels | Pipe Lagging | 525 lf | 5,250 |
| Basements | Pipe Lagging | 358.5 lf | 3,585 |
| Building Interiors | Pipe Lagging | 13,800 lf | 415,000 |
| | Red Flooring ^b (non-friable) | 50,000 sf | 350,000 |
| | or Red Flooring (friable) | 50,000 sf | 1,000,000 |
| Exterior Steam | Pipe Lagging | 880 lf | 30,000 |
| Total Capital Cost (if red flooring is non-friable) | | | 803,835 |
| Total Capital Cost (if red flooring is friable) | | | 1,453,835 |
| O&M Cost (per yr) | | | 15,000 |

^a The estimated removal costs include all costs associated with removal of ACM. These services include development of specifications, canvassing of three competent contractors, asbestos removal, transportation, contractor monitoring, air monitoring, and disposal. These costs assume union labor; mobilization/demobilization from St. Louis, Missouri; 1989 pay scales; and \$25 per cubic foot for disposal of ACM in an approved Missouri asbestos landfill.

^b At present only the red flooring in the three warehouse buildings (219A, D, and G) has been sampled. ICF KE has assumed that red flooring throughout the facility is ACM. The cost estimate provided for the flooring also assumes that the flooring can be removed as non-friable ACM without the need for polyethylene enclosures, HEPA air traps, etc. If the ACM can only be removed as a friable material, complete enclosures will be necessary. The cost would then be better estimated at \$20 per square foot for a total of \$1,000,000 for the removal of 50,000 square feet of red flooring.

The estimated 13,800 linear feet of pipe lagging associated with the buildings and 880 linear feet of exterior steam pipe would cost \$445,000 to remove (See Exhibit 7-3). If the bulk of flooring in the buildings is regarded as nonfriable material, then despite the large volume removal should cost on the order of \$350,000. If the red flooring is characterized as friable material, removal will cost an estimated \$1,000,000. It is estimated that 5 percent of the linear ACM in the tunnels and basements requires repair (880 linear feet) and that none of the thermal jackets require repair. Removal activities when repair is impossible are expected to cost \$10 per linear foot and total approximately \$8,800. The O&M program should cost \$15,000 to maintain. Thus, the total estimated cost of Option II is \$803,835 if the red flooring can be removed as a non-friable material or \$1,453,835 if the red flooring must be removed as a friable material.

5. Option III

In this option all ACM would be removed, resulting in no need for an O&M program. The major cost variable relates to the red flooring and whether it requires removal as a non-friable or a friable ACM. Total costs were developed for removal of all ACM from the facility based on characterizations of the red flooring as non-friable ACM (\$1,426,000) or friable ACM (\$2,076,000). Cost data are presented in Exhibit 7-4.

7.1.2 Contaminated Tunnel System Water

Access to the tunnels and basements from the eastern side of Goodfellow Boulevard should be permanently blocked. Further study of effects from past discharges and determination of contaminant sources may also be necessary, as described below.

7.1.3 Surface Soils

No action to specifically address contaminated soils is recommended, except for enhanced restrictions on access to the site. Demolition activities or continuous occupancy of the area will require reassessment of potential exposures and health risks, and specific protocols to minimize on-site and off-site migration and exposures.

7.1.4 Buildings and Structures

At a minimum, buildings should be repaired to minimize inflow of rainfall and resulting runoff (via the surface or tunnels) of contamination. Demolition of former production Buildings 218A, 218B, and 218C and filling/capping of the basement cavities should be considered to further reduce these contaminant sources. Demolition of buildings within the magazines where contamination has been found also should be considered. Long-term planning should address whether the basements of buildings, if properly engineered, could be permitted as an approved on-site asbestos landfill.

The powder wells and associated piping should be characterized to determine whether contamination is present, then excavated and disposed. Depending on the certainty of the sampling, some of these structures might be filled with clay or concrete as an acceptable remedy.

7.1.5 PCB Transformer and Contaminated Soil

The level of PCBs in the soil sample collected from beneath the transformer at bunker 228C (17,900 ppm of PCB-1260) exceeds the action levels described in Subpart G of TSCA regulations (40 CFR 761.120). Abatement actions for this PCB release are currently being carried out in accordance with applicable regulations. The remedial response must be documented and records maintained for 5 years.

EXHIBIT 7-4

ESTIMATED REMOVAL COSTS FOR ASBESTOS CONTAINING MATERIALS (ACM)^a

OPTION III

| Location | Type of ACM | Amount to be Removed | Cost (\$) |
|---|---|-----------------------------|------------------|
| Tunnels | Pipe Lagging | 10,500 lf | 350,000 |
| Basements | Pipe Lagging | 7,170 lf | 215,000 |
| | Thermal Jackets | 360 sf | 10,000 |
| Building Interiors | Pipe Lagging | 13,800 lf | 415,000 |
| | Red Flooring ^b (non-friable) | 50,000 sf | 350,000 |
| | or Red Flooring (friable) | 50,000 sf | 1,000,000 |
| 227 Bunkers (11 total) | Exterior Transite Siding | 5,600 sf | 56,000 |
| Exterior Steam | Pipe Lagging | 880 lf | 30,000 |
| Total Capital Cost (if red flooring is non-friable) | | | 1,426,000 |
| Total Capital Cost (if red flooring is friable) | | | 2,076,000 |

^a The estimated removal costs include all costs associated with removal of ACM. These services include development of specifications, canvassing of three competent contractors, asbestos removal, transportation, contractor monitoring, air monitoring, and disposal. These costs assume union labor; mobilization/demobilization from St. Louis, Missouri; 1989 pay scales; and \$25 per cubic foot for disposal of ACM in an approved Missouri asbestos landfill.

^b At present only the red flooring in the three warehouse buildings (219A, D, and G) has been sampled. ICF KE has assumed that red flooring throughout the facility is ACM. The cost estimate provided for the flooring also assumes that the flooring can be removed as non-friable ACM without the need for polyethylene enclosures, HEPA air traps, etc. If the ACM can only be removed as a friable material, complete enclosures will be necessary. The cost would then be better estimated at \$20 per square foot for a total of \$1,000,000 for the removal of 50,000 square feet of red flooring.

7.2 RECOMMENDATIONS FOR FURTHER STUDIES

Based on the limited soil sampling performed in this investigation and in earlier investigative work at the site, the nature of contamination found dictates further study to quantify the need for remedies. Inspection of building perimeters and confirmatory soil sampling to depths of 10-20 feet should be performed. The study area should include: Building 220, Building 218, Building 219E, Buildings 219B, 219C, 219F, 219H, and 219J.

Earlier studies and reports provide inconclusive information on Hanley Area structures and their level of contamination. Structures that remain unclear regarding the extent of contamination and their roles in the overall remedial requirements at the Hanley Area include powder wells, sewer lines, the tunnel system, and many buildings and warehouses. A systematic sampling of building interiors and basements may be necessary, particularly if demolition and disposal is contemplated.

Report completed normally.

INSTALLATION RESTORATION PROGRAM

CHEMICAL REPORT

Tue Oct 15 11:56:28 1991

For Parameters :

Installation = St. Louis Ordnance Plant

Beginning Date = 01-jun-90

Ending Date = 15-oct-91

Media Type = Chemical Soil

Maximum (X, Y) = (737959, 4286588)

Minimum (X, Y) = (737373, 4286000)

Booleans = Y

Oct 15, 1991

Installation: St. Louis Ordnance Plant
 Analytical Results for Chemical Soil

| 4085-X | Pipe lagging SW corner/219A | 15-30% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |

^a Asbestos survey conducted by Directorate of Engineering and Housing, US Army Engineer Center and Ft. Leonard Wood.

EXHIBIT B-1 (Continued)

**DATA FROM ECOSAFE ASBESTOS CONTAINING MATERIAL SURVEY
SAMPLE LOCATIONS AND ANALYTICAL RESULTS^a**

| SAMPLE DESIGNATION | DESCRIPTION/LOCATION | ANALYTICAL RESULTS |
|---------------------------|-----------------------------------|---|
| 4085-Y | Pipe lagging NW side/219D | 15-30% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |
| 4085-Z | Pipe fitting NE corner/219D | 5-15% Asbestos (Amosite) 30-50% Asbestos (Chrysotile) |
| 4085-AA | Pipe lagging E side/219D | 15-30% Asbestos (Amosite) 30-50% Asbestos (Chrysotile) |
| 4085-BB | Pipe lagging SE corner/219D | 15-30% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |
| 4085-CC | Pipe lagging E side of N end/219G | 15-30% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |
| 4085-DD | Pipe lagging N side of W end/219G | 15-30% Asbestos (Amosite) 30-50% Asbestos (Chrysotile) |
| 4085-EE | Pipe lagging W side of N end/219G | 30-50% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |
| 4085-FF | Pipe fitting NE corner/219G | >75% Asbestos (Chrysotile) |
| 4085-GG | Pipe lagging NW corner/219A | 15-30% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |
| 4085-HH | Pipe lagging E side/219D | 30-50% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |
| 4085-II | Pipe lagging E side of N end/219G | 15-30% Asbestos (Amosite) 15-30% Asbestos (Chrysotile) |
